Danksagung

Ich möchte mich herzlichst bei Herrn Dr. Nikolaus Wick und Herrn Prof. Stefan Thurner für die Aufnahme in die wissenschaftliche Arbeitsgruppe bedanken. Mein weiterer Dank gilt dem Vorstand des Institutes für klinische Pathologie, Herrn Prof. Dr. Donscho Kerjaschki, für die Bereitstellung des Arbeitsplatzes.

Es ist mir ein großes Anliegen mich bei meinem Betreuer Herrn Dr. Nikolaus Wick für seine tatkräftige und vor allem freundliche Unterstützung während der gesamten Dauer meiner Diplomarbeit zu bedanken. Dankbar bin ich auch den Projektmitgliedern Aurea, Dejan, Dani, Hanni, und Elisabeth für die konstruktive und freundschaftliche Zusammenarbeit. Frau Romana Kalt danke ich für ihre ständige Hilfsbereitschaft und wertvollen Ratschläge bei im Labor auftretenden Problemen. Bedanken möchte ich mich auch bei den Mitgliedern der einzelnen Arbeitsgruppen des Institutes für klinische Pathologie, die mir im Laufe meiner Diplomarbeit mit Rat und Tat zur Seite gestanden haben.

Ganz besonders möchte ich meinen Eltern Leopoldine und Erwin Thader sowie meiner Lebenspartnerin und Freundin Mag. Nicole Jezek für die ständige Unterstützung und den fortwährenden Glauben an mich danken.

1 Abstract

Diabetic microangiopathy, a hyperglycaemia-induced damage of blood capillaries of long-term diabetic patients is characterized by thickening of the capillary basement membrane. Diabetic microvascular complications generally affect the eyes (retinopathy), kidneys (nephropathy) and nerves (neuropathy). A gene set consisting of 125 genes, identified by gene expression profiling comparing (i) blood vascular endothelial cells (BECs) derived from tissue samples of diabetic and non-diabetic patients and (ii) BECs cultured *in vitro* under diabetic conditions, as well as by literature search was hypothesized to control these complications. The 125 candidate genes were the basis of a gene network that was assumed to be of functional relevance for diabetic microangiopathy by demonstration of the functional links between the genes involved. One of the identified candidate genes was HOXA3, a member of the family of homeobox genes encoding homeodomain transcription factors. Quantitative real time PCR of cDNA samples derived from total RNA of immortalized human umbilical vein endothelial cells (iHUEVCs) transiently transfected with pIRES2-EGFP carrying the coding sequence of HOXA3 was executed, in order to study the effects of HOXA3 overexpression on the candidate gene set. Thereby, transient expression of HOXA3 was found to result in elevated expression of genes encoding proteins that act in adipocytes or are involved in reorganization of the actin cytoskeleton. In a final gene network comprising 37 genes and relevant to diabetic microangiopathy, expression of HOXA3 was positively regulated by CFL1 encoding cofilin 1 and downregulated by CASP3 coding for caspase 3. CFL1 a member of the family of actin depolymerising factor (ADF)/cofilins is known to contribute to cytoskeletal dynamics in nonmuscle cells whereas CASP3 encodes an effector caspase that mediates apoptosis of β -cells of the pancreas. Furthermore, it was found that HOXA3 may also have an activating effect on its own expression.

The number of functional links to other genes involved determined the position of a gene within our network. Genes occupying a central position were thought to be key players in the occurrence of microvascular complications since they had a higher number of functional links than genes placed in a peripheral position. In our gene network assumed to be of relevance for diabetic microangiopathy, HOXA3 occupied a peripheral position.

2 Zusammenfassung

Unter diabetischer Mikroangiopathie versteht man den durch Hyperglykämie verursachten Schaden an Blutkapillaren von Patienten, die über einen längeren Zeitraum unter erhöhtem Blutglukosespiegel stehen. Eine Verdickung der kapillären Basalmembran ist charakteristisch für das Auftreten dieser mikrovaskulären Komplikationen, die im Allgemeinen in den Kapillaren der Augen (Retinopathie) und der Nieren (Nephropathie) sowie in den Nerven (Neuropathie) zu finden sind. Basierend auf sowohl vergleichender Analyse der Genexpression in Blutgefäßendothelzellen (BECs) von Diabetikern und gesunden Menschen, sowie in BECs, die *in vitro* unter diabetischen Bedingungen kultiviert wurden, sowie durch Literatursuche konnten 125 Kandidatengene identifiziert werden, von denen man annahm, das Auftreten diabetischer Mikroangiopathie zu kontrollieren. Diese 125 Gene sollten die Grundlage für ein Gennetzwerk bilden, mit dessen Hilfe die genregulatorischen Interaktionen dargestellt werden konnten, welche für das Eintreten von diabetischen mikrovaskulären Komplikationen verantwortlich sind. Unter den identifizierten Kandidatengenen befand sich HOXA3, ein Mitglied der Familie von Homöoboxgenen, die für Transkriptionsfaktoren mit einer Homöodomäne kodieren. Um die Auswirkung der Überexpression des HOXA3 Gens auf die Expression der Kandidatengene zu untersuchen, wurden immortalisierte BECs einer humanen Nabelschnurvene (iHUEVCs) transient mit dem Expressionsvektor pIRES2-EGFP, der die kodierende Sequenz von HOXA3 enthielt, transfiziert. Nach Isolation der gesamten RNA und reverser Transkription, wurde die resultierende cDNA Probe einer quantitativen real time PCR unterzogen. Durch die quantitative real time PCR konnte gezeigt werden, dass infolge einer Überexpression des HOXA3-Gens die Expression solcher Gene stark erhöht wurde, welche entweder in Adipozyten aktiv sind oder eine Rolle bei der Reorganisation des Aktinzytoskeletts spielen.

In dem von uns gestalteten, 37 Gene umfassenden Netzwerk, wurde die Expression von HOXA3 zum einen durch CFL1 positiv reguliert und zum anderen durch CASP3 inhibiert. CFL1 kodiert für Cofilin 1, ein Aktin bindendes Protein, das zur zytoskelettalen Dynamik in Nicht-Muskelzellen beiträgt, während das Genprodukt von CASP3, eine Effektorkaspase, den programmierten Zelltod von β -Zellen des Pankreas herbeiführt.

Die Position eines jeden Gens innerhalb des Netzwerks wurde durch die Zahl seiner direkten funktionellen Verknüpfungen mit anderen Genen bestimmt. Dabei waren jene Gene mit den meisten direkten funktionellen Verknüpfungen im Zentrum angeordnet, und ihnen wurde deshalb auch eine zentrale Rolle bei der Entstehung von diabetischen mikrovaskulären

Komplikationen beigemessen. Das HOXA3 Gen besetzte gemäß der Anzahl seiner direkten funktionellen Verknüpfungen eine periphere Position innerhalb des 37 Gene umfassenden Netzwerks.

3 Introduction

3.1 Diabetes mellitus and diabetic microangiopathy

3.1.1 Diabetes mellitus

Diabetes mellitus is a metabolic disorder existing in different forms, all of which are characterized by hyperglycaemia. In fact, diabetes mellitus is diagnosed in patients with fasting plasma glucose levels above 126 mg/dl (7.0mmol/l) or casual plasma glucose levels above 200mg/dl (11.1mmol/l).

Mechanisms contributing to the occurrence of hyperglycaemia are known to be failures in either action or secretion or both of the glucose-lowering pancreatic hormone insulin. A permanent state of hyperglycaemia causes various dysfunctions and defects of organs including the eyes (retinopathy), kidneys (nephropathy), nerves (neuropathy) and heart (cardiomyopathy). Clinical symptoms associated with the occurrence of hyperglycaemia are known to be polyuria, polydipsia and weight loss. In some cases, polyphagia, impaired vision and susceptibility to certain infections may be indicators of hyperglycaemia.

Patients suffering from diabetes mellitus bear an increased risk for atherosclerotic cardiovascular, peripheral arterial and cerebrovascular disease.

Several forms of diabetes mellitus are known, the three major types are type 1 diabetes, type 2 diabetes and gestational diabetes.

Type 1 diabetes, also referred to as insulin-dependent diabetes or juvenile-onset diabetes, is an autoimmune disease and occurs as the result of absolute insulin deficiency due to autoimmune destruction of insulin-producing pancreatic β -cells. Although type 1 diabetes can appear at any age, persons usually affected are children and adolescents. People with this form of diabetes require insulin for survival and therefore have to take insulin by injection up to several times a day. Type 1 diabetes accounts for 5-10 % of all patients suffering from diabetes. Markers identified for the autoimmune destruction of the β -cells of the pancreas are several autoantibodies targeted to islet cells, to insulin, to glutamic acid decarboxylase (GAD₆₅) and to tyrosine phosphatases IA-2 and IA-2 β . Diabetic ketoacidosis (DKA), defined as a state characterized by hyperglycaemia, accumulated ketone bodies in the blood as well as increased acidity of the blood, is a life-threatening condition that can occur as a result of insulin deficiency. Diabetic ketoacidosis is commonly found in people with type 1 diabetes, although it can also happen to patients suffering from type 2 diabetes. Although the causes of

type 1 diabetes are widely unknown, it is believed that genetic predispositions and environmental factors may play a decisive role in the development of the disease. Another rare form of type 1 diabetes, referred to as idiopathic diabetes, is commonly found in people of African or Asian descent. In contrast to autoimmune mediated type 1 diabetes described above, this form is not characterized by autoimmune destruction of the β -cells of the pancreas, but rather by a lack of β -cell autoimmunity markers.

The most prevalent form of diabetes is **type 2 diabetes** that accounts for 90-95% of all diabetes cases. Type 2 diabetes is also referred to as non-insulin dependent diabetes or adult-onset diabetes and occurs as the result of insulin resistance and relative insulin deficiency. In contrast to type 1 diabetes, there is no autoimmune destruction of pancreatic β -cells found in patients with type 2 diabetes. In many cases, type 2 diabetes remains unnoticed for years due to a gradual emergence of hyperglycaemia. Risk factors identified for type 2 diabetes include obesity, low physical activity and advanced age. Furthermore, the occurrence of type 2 diabetes is often linked to genetic predisposition. Unlike people suffering from type 1 diabetes, patients with type 2 diabetes often do not depend on insulin treatment for survival. Glucose intolerance that arises or is first noticed during pregnancy is also known as **gestational diabetes mellitus (GDM)**. Several factors including obesity, a family history of diabetes, abnormal glucose metabolism before pregnancy and being a member of an ethnic group with a high incidence of diabetes are known to increase the risk for women of developing this form of diabetes. In the majority of cases, women affected by GDM are older than 25 years indicating the influence of age on the development of GDM (American Diabetes Association, 2007).

On the long term the result of all types of diabetes may be macrovascular and microvascular complications. In this thesis, only microangiopathic damage is dealt with.

3.1.2 Diabetic microangiopathy

Diabetic microangiopathy is a glucose-induced damage of blood capillaries of long-term diabetic patients. It is characterized by thickening of the capillary basement membrane. These diabetic microvascular complications are found in the eye (retinopathy) and in the kidney (nephropathy), and they are also involved in neuropathy. Besides direct damage to parenchymal cells, capillary damage is the most important mediator of organ dysfunction. Hyperglycaemia considered as the primary initiating factor for all types of diabetic microvascular disease seems to be responsible for several mechanisms characteristic for the

occurrence of diabetic microangiopathy. These mechanisms include structural, functional and biochemical changes. Structural changes in the form of thickening of the capillary basement membrane can result in occlusive angiopathy, tissue hypoxia and damage. Functional changes include increases in organ blood flow and vascular permeability, as well as abnormalities in blood viscosity, platelet and endothelial function (K Dahl-Jørgensen, 1998). Finally, four biochemical mechanisms are known to contribute to microvascular complications in diabetes, all of them induced by hyperglycaemia (Brownlee, 2001; Schalkwijk and Stehouwer, 2005).

Increased polyol pathway flux is one biochemical mechanism typical for the occurrence of diabetic vascular diseases. In the beginning of this pathway, the enzyme aldose reductase catalyzes the NADPH-dependent reduction of glucose to sorbitol. Under non-diabetic conditions, metabolism of glucose by the polyol pathway occurs at very low rates due to a low affinity of the enzyme aldose reductase for glucose. However, hyperglycaemia leads to increased conversion of intracellular glucose to sorbitol accompanied by an increase in oxidation of NADPH to NADP^+ . Another enzyme of the polyol pathway, sorbitol dehydrogenase catalyzes the oxidation of sorbitol to fructose with simultaneous reduction of NAD^+ to NADH. Although there are many hypotheses about the damaging effects the products of the polyol pathway may have on cells, the role of this pathway in diabetic microvascular complications is not completely understood yet (Brownlee, 2001). The most plausible mechanism by which increased polyol pathway flux damages cells is based on the assumption that NADPH-dependent reduction of glucose to sorbitol depletes NADPH which in turn is essential for regeneration of reduced glutathione (GSH). The consequence of this NADPH consumption is oxidative stress (Lee and Chung, 1999).

Another biochemical mechanism induced by hyperglycaemia and critical for microvascular complications in diabetes is the **increased intracellular formation of advanced glycation end products (AGEs)**. Non-enzymatic glycation of proteins, defined as the condensation reaction of a sugar aldehyde or ketone with a free amino group by nucleophilic addition, leads to formation of a Schiff base which rearranges to the Amadori product. In the final step, the irreversible advanced glycation end product (AGE) is formed (Brownlee et al., 1990).

Originally, non-enzymatic glycation reactions involving extracellular proteins and glucose were considered to be decisive for the production of AGEs. However, dicarbonyl precursors derived from glucose and generated intracellularly have been shown to form AGEs much faster suggesting that intracellular hyperglycaemia plays the central role in the formation of intracellular as well as extracellular AGEs. The highly reactive dicarbonyl compounds are known to be glyoxal, methylglyoxal and 3-deoxyglucosone which are formed from glycolytic

intermediates and react with extracellular and intracellular proteins to form AGEs (Wells-Knecht et al., 1995; Degenhardt et al., 1998). Methylglyoxal arising from glyceraldehyde-3-phosphate is thought to be the main AGE-precursor in endothelial cells and therefore plays a critical role in the development of vascular complications in diabetes mellitus (Bourajjaj et al., 2003).

Production of intracellular AGE precursors results in intracellular as well as extracellular alterations (Figure 1).

Figure 1. Mechanisms induced by production of intracellular AGE precursors alter gene expression in endothelial cells, mesangial cells and macrophages. Modifications of several proteins including intracellular, extracellular matrix and plasma proteins by intracellular AGE precursors are the basis of these alterations (Brownlee, 2001).

AGE formation on extracellular matrix proteins has been shown to influence interactions of these proteins with their respective receptors (integrins) on cells and other matrix components (Brownlee, 2001). Matrix proteins known to be targets of AGE formation are type I and type IV collagen as well as laminin. Type IV collagen and laminin are major components of the basement membrane and necessary for the maintenance of its normal structure and function. Therefore, AGE formation on these proteins impairs matrix-matrix as well as cell-matrix interactions (Tanaka et al., 1988; Tsilibary et al., 1988; Charonis et al., 1990). Another mechanism induced by binding of AGE modified plasma proteins to AGE receptors leads to altered gene expression in endothelial cells, mesangial cells and macrophages. AGE binding proteins identified on these cells and targeted by AGE modified plasma proteins are RAGE, galectin-3, the macrophage scavenger receptor type II, OST-48 and 80K-H (Neeper et al., 1992; Vlassara et al., 1995; Smedsrod et al., 1997; Li et al., 1996). Binding to RAGE has been found to generate reactive oxygen species (ROS) resulting in the activation of the transcription factor NF- κ B and p21^{Ras} (Yan et al., 1994; Lander et al., 1997). In mesangial cells and macrophages, AGE signalling leads to expression of various cytokines and growth factors such as IL-1, TNF- α and TGF- β (Schalkwijk and Stehouwer, 2005). Binding of AGE-

modified proteins to their receptors on endothelial cells induces expression of pro-coagulatory and pro-inflammatory molecules known to be thrombomodulin, tissue factor and the vascular cell adhesion molecule VCAM-1 (Schmidt et al., 1995; Brownlee, 2001). Furthermore, it has been found that AGE signalling in endothelial cells may induce VEGF and therefore seems to contribute to diabetes induced hyperpermeability of the capillary wall (Lu et al., 1995).

The third mechanism contributing to diabetic microvascular diseases leads to **activation of protein kinase C (PKC)**. Hyperglycaemia leads to increased formation of the activator of PKC, the lipid second messenger diacylglycerol (DAG). The PKC family includes at least eleven isoforms. Although DAG has been found to activate almost all of them, its primary targets are the β - and δ -isoforms. Hyperglycaemia-induced *de novo* synthesis of DAG is achieved by reduction of the glycolytic intermediate dihydroxyacetone phosphate to glycerol-3-phosphate followed by acylation reactions (Koya and King, 1998).

Activation of PKC affects the expression of numerous genes resulting in various structural and functional changes typical for microvascular complications in diabetes. Abnormalities in blood flow are the result of inhibition of eNOS (Kuboki et al., 2000) and activation of ET-1, both mediated by PKC (Glogowski et al., 1999). PKC activation has been found to induce VEGF leading to vascular permeability and angiogenesis (Williams et al., 1997). Capillary occlusion is the consequence of PKC mediated induction of TGF- β , fibronectin and collagen (Koya et al., 1997). PKC activation has been shown to cause vascular occlusion by activation of PAI-1 resulting in inhibition of fibrinolysis (Feener et al., 1996). Further genes found to be induced as a result of PKC activation are NF κ B (Pieper et al., 1997) and NAD(P)H oxidases. The former activates expression of pro-inflammatory genes and the latter induces ROS leading to multiple effects.

The fourth biochemical pathway found to be relevant to diabetic microvascular complications is the **hexosamine pathway**. In this pathway, the enzyme glutamine:fructose-6-phosphate amidotransferase (GFAT) catalyzes the conversion of the glycolytic intermediate fructose-6-phosphate to glucosamine-6-phosphate which is subsequently converted into UDP-N-acetylglucosamine (UDPGlcNAc). UDPGlcNAc is required for O-linked glycosylation of proteins catalyzed by the enzyme O-GlcNAc transferase (OGT). Hyperglycaemia-induced increased flux through the hexosamine pathway has been found to result in increased expression of TGF- β 1 (Kolm-Litty et al., 1998) and PAI-1 (Du et al., 2000). The mechanism responsible for elevated expression of TGF- β 1 and PAI-1 is suggested to increase covalent modification of serine and threonine residues of transcription factors such as Sp1 by N-

acetylglucosamine. Furthermore, inhibition of eNOS activity has been shown to occur by O-acetylglucosamylation at the Akt site of the protein (Du et al., 2001).

The four biochemical pathways described above have in common that they are activated by hyperglycaemia-induced oxidative stress (Figure 2). It has been found that hyperglycaemia leads to overproduction of superoxide O_2^- by the mitochondrial electron transport chain (Du et al., 2000). This is the result of hyperglycaemia-induced increased amounts of electron donors NADH and $FADH_2$ from the TCA cycle. According to these elevated levels of electron donors, the electron flow through the mitochondrial electron transport chain generates a high proton gradient across the inner mitochondrial membrane. The consequence of the increased mitochondrial membrane potential is a prolonged half-life of superoxide-producing ubiquinone of the mitochondrial electron transport chain (Brownlee, 2001). The overproduction of superoxide has been found to result in activation of the enzyme PARP which in turn inhibits the glycolytic enzyme GAPDH by poly-ADP-ribosylation (Du et al., 2003).

Figure 2. Hyperglycaemia-induced oxidative stress activates four biochemical pathways that are known to contribute to vascular complications in diabetes. Overproduction of superoxide activates the enzyme PARP which in turn inhibits the glycolytic enzyme GAPDH by poly-ADP-ribosylation resulting in accumulation of upstream glycolytic metabolites and activation of the four biochemical pathways (Schalkwijk and Stehouwer, 2005).

3.1.3 Identification of a gene network relevant to diabetic microangiopathy

In contrast to the biochemical mechanisms, there is only little knowledge about the genetic factors contributing to the development of diabetic microangiopathy. Therefore, the aim of diabetic research is the development of genetic markers for diabetic microangiopathy by finding genes that are associated with the occurrence of microvascular complications in diabetes (K Dahl-Jørgensen, 1998).

A cooperation project between the Institute for Pathology and the Complex Systems Research Group, both from the Medical University of Vienna, has been initiated, in order to identify a functionally relevant gene network critical for diabetic microangiopathy.

3.1.4 Preexisting data

The basis for this network is a set of 125 candidate genes that has been found by gene expression profiling comparing (i) BECs derived from tissue samples of diabetic and non-diabetic patients and (ii) BECs cultured *in vitro* under diabetic conditions, as well as by literature search.

The aim of identifying a gene network critical for diabetic microangiopathy is to display the functional links between the candidate genes representing upregulating and downregulating effects as well as autoregulatory mechanisms.

In order to examine the role of a candidate gene within a supposed gene network the gene has to be transiently expressed in an appropriate cell line. Total RNA isolated from cells overexpressing a certain gene is converted to cDNA by reverse transcription and applied to TaqMan Low Density Arrays spotted with primers and probes for all candidate genes. Subsequent quantitative real time PCR enables quantitative detection of PCR products after numerous PCR reactions carried out simultaneously according to the number of candidate genes. Finally, the upregulating and downregulating effects of a certain transiently expressed gene within the candidate gene set on the rest of this set can be measured. According to overexpression data, special computer software developed by the Complex Systems Research Group is used to create a gene network by reverse engineering. More precisely, a mathematical algorithm capable of reconstructing a network comprising a defined number of candidate genes is built. In order to identify the functional links between candidate genes within an assumed network, the expression of these genes is perturbed in the form of overexpression experiments. Gene expression dynamics or changes in expression level with

respect to time (dX/dt) of candidate genes within a network resulting from transient expression of one candidate gene are described as follows:

$$dX/dt = f(A, X)$$

In this formula X comprises all candidate genes within the network ($X_1, X_2, X_3, \dots, X_n$) and the adjacency matrix A represents the functional links between the candidate genes.

In case of a steady state meaning a state of unaltered gene expression dX/dt can be set equal to zero.

3.2 The HOX gene family

3.2.1 General features of HOX genes

Homeobox (HOX) genes encode transcription factors, all of them possessing a so called homeodomain that has a DNA binding function. More precisely, the homeodomain is responsible for binding to specific sequences within the promoter region resulting in transcriptional regulation of the corresponding target genes (Levine and Hoey, 1988).

A total of 39 HOX genes organized in four clusters named A, B, C and D are found in mammals, whereas each cluster is located on a different chromosome. Another feature of HOX genes is the existence of 13 paralogue groups. Therefore each cluster is numbered from 1 to 13. Still, no one contains a full set of HOX genes (Claudia Kappen et al., 1989; Scott, 1992). Genes of the same group, referred to as *trans*-paralogues, are equally numbered and show a high degree of sequence. They are located on different chromosomes but occupy the same relative position. *Cis*-paralogues are adjacent on the same chromosome, i.e. within the same cluster (Greer et al., 2000). In the evolution of HOX genes, two steps occurred, resulting in the formation of the existing paralogue groups. In the first step, a primordial homeobox gene cluster complex was amplified in *cis*, whereas the second involved *trans*-duplication (Claudia Kappen et al., 1989).

3.2.2 Function of HOX genes

HOX genes were initially discovered in *Drosophila melanogaster* where they are known to act in anterior-posterior axis patterning during embryogenesis (Lewis, 1978; Ingham, 1988).

Further studies carried out with mammalian species have revealed that HOX genes also have an important function in adult cells in addition to their roles during embryonic development. Genes regulated by HOX transcription factors are critical for a number of cellular processes (Figure 3). These are organogenesis, cellular differentiation, cell adhesion and migration, cell cycle and apoptosis (Ulijaszek et al., 1998).

The individual paralogues of HOX genes can have complementary, overlapping or completely different functions. As already mentioned *trans*-paralogues show a high degree of sequence homology, and sometimes have a functional overlap, whereas *cis*-paralogues differ more in terms of sequence and function. In some cases, *trans*-paralogues, such as HOXA3 and HOXD3 have been shown to carry out identical functions. Embryonic HOXA3 null mice, which are homozygous for the HOXA3 null mutation and therefore do not express any HOXA3 protein, experience perinatal lethality that can be rescued by the introduction of HOXD3 into the HOXA3 locus. HOXA3 introduced into the HOXD3 locus by homologous recombination, has in turn rescued mice homozygous for HOXD3 null mutation, thereby preventing skeletal defects of atlas and axis. Interestingly, introduction of HOXA3 into the HOXD3 locus does not compensate the effects of homozygous HOXA3 null mutation on embryonic development. These data suggest that HOXA3 and HOXD3 can exhibit functional equivalence under certain circumstances only, although they do not have identical functions under normal conditions. However, the difference in biological functions between *trans*-paralogues, such as HOXA3 and HOXD3 does not seem to be a matter of different qualities of the respective genes. Otherwise, HOXA3 introduced into the HOXD3 locus would rescue embryonic mice, homozygous for HOXA3 null mutation. It is more plausible that their differential roles are the result of differences in their expression levels due to *cis*-acting sequences, controlling the expression of the respective loci (Greer et al., 2000; T Svingen and KF Tonissen, 2006)

Figure 3. Mammalian target genes of transcription factors encoded by HOX genes and their respective roles in cellular processes. Genes regulated by HOX transcription factors are critical for a number of cellular processes including organogenesis, cellular differentiation, cell adhesion and migration, cell cycle and apoptosis (T Svingen and KF Tonissen, 2006).

3.2.3 The homeodomain

As mentioned above, highly conserved 60 amino acid motif, the homeodomain, is found in transcription factors that are encoded by homeobox genes. Recognizing specific sequences within the promoter region of its target genes, this protein domain has a DNA binding function enabling transcriptional regulation. The homeodomain is encoded by a 180 base pair nucleotide sequence, referred to as the homeobox that is distinctive for homeobox genes (Levine and Hoey, 1988; McGinnis and Krumlauf, 1992).

Three alpha helices forming a helix turn helix motif as well as the N-terminal arm are composing the homeodomain (Kuziora and McGinnis, 1989). A high number of homeodomain proteins are known to bind specifically to a TAAT core sequence. Interaction with DNA is mediated by amino acid residues in the N-terminal arm and third helix. Thereby the N-terminal arm interacts with DNA in the minor groove, whereas the third helix contacts the major groove (Figure 4). X-ray crystallography and nuclear magnetic resonance

spectroscopy have been used to come to this conclusion. Basic residues 3 and 5, both located on the N-terminal arm have been found to contact the nucleotides A₂ and T₁ respectively of the TAAT core sequence. On the third helix, a hydrophobic residue numbered 47 and a conserved asparagine (Asn) at position 51 have been identified to interact with T₄ and A₃ respectively of the DNA recognition sequence (Desplan et al., 1988; Qian et al., 1989; Kissinger et al., 1990; Otting et al., 1990).

Figure 4. Structure of the homeodomain. The homeodomain is composed of an N-terminal arm and three alpha helices that form a helix turn helix motif. Amino acid residues in the N-terminal arm and in helix 3 mediate interaction with DNA in the minor and the major groove respectively. Numbers of amino acid residues interacting with the TAAT core sequence are shown (T Svingen and KF Tonissen. 2006).

3.2.4 HOXA3

A certain member of the HOX gene family, HOXA3 has been found to be of great importance for the development of thymus, thyroid and parathyroid in embryonic mice. Mice homozygous for HOXA3 mutation are characterized by the absence of thymus and parathyroids, as well as by thyroid hypoplasia. Embryonic HOXA3 is expressed in neural

crest derived mesenchymal cells of the pharyngeal arches and in the pharyngeal endoderm. These regions are known to give rise to thymus, thyroid and parathyroid explaining the strong influence of HOXA3 on the development of these structures. According to further studies, the transcription factors HOXA3 and PAX1 are necessary for the development of thymic epithelial cells which interact with thymocytes, in order to promote thymocyte maturation into T-cells. Mice heterozygous for HOXA3 and homozygous for PAX1 mutation have defects in thymic epithelial cell development. Decreased MHC class II expression and impaired capability to promote thymocyte development are typical for thymic epithelial cells of these mutants (Manley and Capecchi, 1995; Manley and Capecchi, 1998; Dong-ming Su and Manley, 2000).

Further studies have revealed that HOXA3 expression leads to cell migration in endothelial and epithelial cells. The consequence is an activity promoting both, angiogenesis and wound closure. Constitutive expression of HOXA3 in an immortalized human dermal microvascular endothelial cell line HMEC-1 has shown that HOXA3 causes upregulation of genes involved in cell-cell and cell-extracellular matrix (ECM) interactions. These genes, such as uPAR and MMP-14 are important for an increase of the angiogenic potential of endothelial cells by degradation of ECM-constituents. HOXA3 has been found to be upregulated in wounded tissues of mice, where it promotes angiogenesis in order to initiate wound repair. Interestingly, further studies have revealed a lack of HOXA3 in wounds of diabetic mice. However, transfer of HOXA3 expression plasmids into the wounded diabetic tissue has resulted in upregulation of uPAR and MMP-14, leading to accelerated wound closure. These data suggest a therapeutic value of HOXA3 for diabetic patients *via* its activity in endothelial cells (Kimberly et al., 2005).

HOXA3 also seems to play a role in diabetic microangiopathy, a process characterized by thickening of the capillary basement membrane of patients suffering from diabetes mellitus. A candidate gene set containing 125 genes, including HOXA3 has emerged to be of relevance to diabetic microangiopathy. This gene set has been identified by gene expression profiling comparing (i) BECs derived from tissue samples of diabetic and non-diabetic patients and (ii) BECs cultured *in vitro* under diabetic conditions, as well as by literature search. HOXA3 has been found to be upregulated under diabetic conditions (Nikolaus Wick et al., unpublished data). Furthermore, HOXA3 constitutively expressed in HMEC-1 leads to upregulation of collagen, type VI, alpha 1 (Kimberly et al., 2005). Thickening of the capillary basement membrane during diabetic microangiopathy is characterized by increases in type IV and type

VI collagen (Williamson JR, Tilton RG et al., 1988), suggesting a possible significance of HOXA3 for this process.

One aim of this diploma thesis is to report the role of transcription factor HOXA3 in diabetic microangiopathy by examining its effects upon transient expression in immortalized human umbilical vein endothelial cells (iHUEVCs) on the genes within the candidate set. Another aim is to identify the position of the HOXA3 gene in a gene network that is assumed to be of relevance to diabetic microangiopathy.

4 Materials and methods

4.1 Buffers and solutions

4.1.1 Buffers and solutions for molecular biological methods

LB (Luria Broth) medium

10 g Bacto-tryptone (DIFCO, USA, cat. no. 211705)

5 g Bacto-yeast extract (DIFCO, cat. no. 212750)

10 g NaCl

1N NaOH was added until pH was adjusted to 7.5.

Water was then added to a final volume of 1000 ml. Finally, medium was autoclaved and cooled down to 50-55°C.

LB (Luria Broth) agar plates

700 ml LB medium (see above)

10.5 g agar (DIFCO, cat. no. 281230)

The mixture was autoclaved and cooled down to 50-55°C.

Antibiotics (30 µg/ml ampicillin, chloramphenicol or kanamycin) were added at a ratio of 1:1000 (700 µl) to yield a final concentration of 30 µg/µl. Afterwards, 20-30 ml volumes of medium were transferred into Petri dishes and the plates were stored at 4°C.

TENS lysis buffer (Plasmid preparation method “Genevieve”)

0.5 ml 1M TRIS-HCl pH 8 (10mM)

100 µl 0.5M EDTA (1mM)

5 ml 1N NaOH (0.1N)

1.15 ml 20%SDS

43.25 ml Distilled water

4.1.2 Buffers and solutions for cell biology methods

Molecular weights

Tris: 121.14 g; Glycine: 75.07 g; EDTA: 380.2 g; DTT: 154.25 g;

1 x PBS (Washing buffer)

0.20 g KCl

0.20 g KH₂PO₄

1.15 g Na₂HPO₄

8.00 g NaCl

Distilled water was added to a final volume of 1000 ml. HCl was used to adjust pH 7.4.

0.1% Triton X-100

50 µl Triton X-100

Addition of 1 x PBS to a final volume of 50 ml

4.1.3 Buffers and solutions for SDS-PAGE/Western blot

1M Tris-HCl pH 6.8/8.8

121.14 g Tris base

1000 ml of double distilled water

Addition of HCl until pH 6.8/8.8 was adjusted

Laemmli Buffer

6.25 ml of 1M Tris-HCl, pH 6.8 (62.5 mM)

2.35 g SDS (2.35%)

0.038 g EDTA (1 mM)

10 ml Glycerol (10%)

0.001 g Bromphenol blue

1.543 g DTT (100 mM)

Water was added to a volume of 1000 ml. Laemmli Buffer containing DTT was aliquoted and stored at -20°C.

12% Acrylamid gel

3.3 ml Distilled water

4.0 ml 30% Acrylamid BIS (29:1, BioRad)

2.5 ml Tris-HCl, pH 8.8

0.1 ml 10% SDS

0.1 ml 10% APS

4.0 µl TEMED (N,N,N',N'-Tetramethylethylenediamine)

Stacking gel

3.4 ml Distilled water

830 µl 30% Acrylamid BIS (29:1, BioRad)

630 µl Tris-HCl, pH 6.8

50 µl 10% SDS

50 µl 10% APS

5 µl TEMED (N,N,N',N'-Tetramethylethylenediamine)

10 x Electrophoresis buffer for SDS-PAGE

360.325 g Glycin (192 mM)

75.7125 g Tris (25 mM)

25 g SDS (0.25%)

Distilled water was added to a volume of 2500 ml. For electrophoresis 10 x electrophoresis buffer was diluted 10 fold.

Transfer buffer for Western blot

36.034 g Glycine (192 mM)

7.571 g Tris (25 mM)

500 ml Methanol (20%)

Distilled water was added to a volume of 2500 ml and pH was adjusted to 8.5.

Ponceau S Red

0.1 % Ponceau S Rot in distilled water

5 % Acetic Acid

10 x TBS (Tris Buffered Saline)

24.5 g Tris

80.0 g NaCl

Distilled water was added to a volume of 1000 ml and pH was adjusted to 7.6

1 x TBS with Tween (TBST)

900 ml Distilled water

1 ml Tween-20

100 ml 10 x TBS

Blocking buffer (5% milk powder in TBST)

5 ml 10 x TBS

45 ml distilled water

2.5 g nonfat dry milk (5%)

50 µl Tween-20

Antibody dilution buffer (2.5% milk powder in TBST)

2 ml 10 x TBS

18 ml distilled water

0.5 g nonfat dry milk (2.5%)

20 µl Tween-20

4.2 Cloning vectors

Two cloning vectors (Figure 5) were used for cloning the coding sequence of the HOXA3 gene:

Figure 5. Cloning vectors used for cloning the coding sequence of the HOXA3 gene were pCR® II TOPO® (5a) and pIRES2-EGFP (5b).

After PCR, the coding sequence of the HOXA3 gene was subcloned into the **pCR® II TOPO® vector** (Figure 5a) that was purchased from Invitrogen. Topoisomerase I isolated from *Vaccinia* virus is covalently attached to the plasmid vector. After recognizing the specific sequence CCCTT on one strand, the enzyme binds to duplex DNA where it cleaves the phosphodiester backbone after the last thymidine (T) of the recognition sequence (Shuman, 1991). Topoisomerase I activity on both strands of the pCR® II TOPO® vector generates single 3'-thymidine (T) overhangs. PCR products generated by Taq polymerase possess single deoxyadenosines (A) at their 3' ends enabling insertion into pCR® II TOPO®. DNA-cleavage by topoisomerase I results in covalent attachment of the enzyme to the 3'phosphate of the cleaved strand of the plasmid vector, as mentioned above. Release of topoisomerase I is achieved by nucleophilic attack of the 5'hydroxyl of the broken strand. Therefore, PCR products require 5'hydroxyl instead of 5'phosphates for successful ligation into the vector (Shuman, 1994).

The pCR® II TOPO® vector has a molecular size of 4.0 kb and contains two antibiotic resistance marker genes that provide resistance to kanamycin and ampicillin. Furthermore, a pUC origin of replication conferring propagation in *E.coli* and an f1 origin for synthesis of single stranded DNA are located on the plasmid vector.

The multiple cloning site resides within the sequence of the lacZ α gene that is connected to the lac promoter. Cloning a DNA sequence into the multiple cloning site leads to interruption of the lacZ sequence resulting in a loss of function of the lacZ α gene to produce the protein beta galactosidase. The fact that beta galactosidase turns its substrate X-gal into a blue dye is used to select for cells that contain plasmid vectors with an interrupted multiple cloning site. In case of successful cloning of a coding sequence into pCR® II TOPO®, transformed cells remain white in presence of X-gal due to interruption of the lacZ α gene. Blue stained cells possess a functional lacZ α gene that turns X-gal into a blue dye. IPTG inactivates the lac repressor resulting in activation of the lac operon. Therefore, addition of IPTG is necessary in order to enable the blue/white selection method.

The coding sequence of the HOXA3 gene was cloned into the expression vector **pIRES2-EGFP** (Figure 5b) purchased from Clontech Laboratories, Inc., in order to study transient overexpression of HOXA3 in immortalized human umbilical vein endothelial cells (iHUEVCs). The characteristic of pIRES2-EGFP is the presence of the internal ribosomal entry site (IRES) of the encephalomyocarditis virus (ECMV). On the expression vector, the internal ribosomal entry site is located between the multiple cloning site and the coding region of the enhanced green fluorescent protein (EGFP). This construction enables translation of the gene that is cloned into the multiple cloning site and the EGFP gene from a single bicistronic mRNA. The multiple cloning site itself is located between the immediate early promoter of cytomegalovirus (P_{CMV IE}) and the IRES sequence

Expression of the EGFP gene indicates successful transfection into iHUEVCs and other eukaryotic cells with pIRES2-EGFP carrying the gene of interest. However, it is important to note that synthesis of the EGFP protein does not require cloning of a gene into the multiple cloning site of the expression vector. Therefore, pIRES2-EGFP may be used for control transfection. Processing of the bicistronic mRNA is directed by SV40 polyadenylation signals located downstream of the EGFP gene. Furthermore, pIRES2-EGFP contains an SV40 origin conferring replication in eukaryotic cells expressing the SV40T antigen.

Another feature of pIRES2-EGFP is the presence of both, a pUC origin of replication enabling propagation in *E.coli* and an f1 origin for synthesis of single stranded DNA. Antibiotic resistance genes confer resistance to kanamycin and neomycin (BD Biosciences Clontech).

4.3 Molecular biology methods

Bacterial cultures

DH10B TonA cultures transformed with plasmid pCMV-Sport6 carrying the HOXA3 gene were purchased as glycerol stock from Invitrogen (cat. no. 3905733). Before starting a PCR, overnight cultures had to be grown by combining 1.0 µl aliquots of the glycerol stock with 4 ml of LB-medium. In order to select for cells containing the pCMV-Sport6 plasmid the antibiotic ampicillin (100 mg/ml) was added at a ratio of 1:1000 to the mixture (final concentration of Ampicillin: 100 µg/ml).

Plasmid DNA isolation (plasmid “miniprep”)

Plasmid miniprep was done for 1.5 ml of each bacterial over night culture. After a quick spin in the Eppendorf Microcentrifuge at 10,000 rpm and following disposal of the supernatant the remaining cell pellet was dissolved in 300 µl of TENS and 150 µl of 3M potassium acetate to cause cell lysis. Then, the lysate was centrifuged for 2 min. at 13,000 rpm (17,900 x g) and the supernatant was transferred into a fresh tube. After adding 900 µl of 96% ethanol the resulting mixture was put on -80°C for 30 min. Afterwards the solution was centrifuged for 20 min. at 4°C and the supernatant was removed. The remaining cell pellet was washed with 900 µl of 70% ethanol and the resulting solution was centrifuged again for 2 min. at 13,000 rpm. After removing the ethanol the pellet was air dried and dissolved in 50 µl DNase free water.

Restriction digestion of pCMV-Sport6

After elution of plasmid DNA in 50 µl DNase free water a restriction digest of an aliquot of 5.0 µl and subsequent gel electrophoresis on 1 % agarose gel containing ethidium bromide were executed in order to control the success of pCMV-Sport6 isolation and to check whether the plasmids carried the right insert. The restriction endonucleases NheI (recognition sequence: GCTAGC) and StuI (recognition sequence: AGGCCT) were used to cut the insert out of pCMV-Sport6. All reagents used for digestion were purchased from New England BioLabs Inc.

The composition of the 20 µl reaction mix was as follows:

- 5.0 µl.....DNA
- 0.5 µl.....RNase
- 1.0 µl.....StuI
- 1.0 µl.....NheI
- 0.2 µl.....BSA (at a ratio of 1:100 to the total volume)
- 2.0 µl.....10 x buffer (NEBuffer 2; at a ratio of 1:10 to the total volume)
- 10.3 µl.....Water (aqua dest.)

The reaction mix was incubated for 1-2 hours at 37°C. Before the samples were applied to the gel, 5.0 µl of loading dye were added.

PCR of HOXA3

Primers for the PCR reaction (also from Invitrogen) were designed with the aid of the OligoPerfect™ Designer program provided by Invitrogen. Primers were designed corresponding to the start and the end of the coding sequence of the HOXA3 gene to ensure that only the coding sequence was amplified during the PCR reaction. Restriction enzyme sites were added to the 5' ends of both, forward and reverse primer. Forward primer contained a restriction site for XhoI (CTCGAG) and an additional 5' CAGT extension leading to a primer sequence as follows: 5'-CAGTCTCGAGATGCAAAAAGCGACCTACTA-3', whereas reverse primer possessed a restriction site for SalI (GTCGAC) and an additional 5' CAGT extension yielding the primer sequence 5'-CAGTGTCGACTCACAGGTGGGTGAGCTTG-3'. Primers diluted 1:10 in distilled water were added to the PCR reaction mix. Primer extension was catalyzed by Taq Polymerase purchased from Pharmacia. PCR was meant to deliver products containing the recognition sequence for XhoI (CTCGAG) on their 5' ends and the recognition sequence for SalI (GTCGAC) on their 3' ends. The whole 50 µl PCR reaction mix was composed of as follows:

- 0.5 µl.....DNA
- 2.0 µl.....dNTPs
- 3.0 µl.....Rapid load
- 5.0 µl.....PCR 10 x buffer (Pharmacia)
- 2.0 µl.....Primer (from 1:10 dilution)
- 0.5 µl.....Taq polymerase (5000 U/ml; Pharmacia)
- 37.0 µl.....Water (aqua dest.)

The PCR program was as follows:

95°C	5 min.	
76°C	2 min.	(Addition of Taq polymerase)
95°C	1 min.	} 40 cycles
60°C	1 min.	
72°C	90 sec.	
72°C	10 min.	
4°C	forever	

PCR was performed by GeneAmp PCR System 9600 for 40 cycles. The expected 1.3 kb PCR product was visualized by electrophoresis on 1% agarose gels containing ethidium bromide.

Extraction of the PCR products from the agarose gel and purification

Extraction and purification of the 1.3 kb PCR products were executed using the QIAquick® PCR Purification Kit from QIAGEN (cat. no. 28104). Three volumes of gel dissolving buffer QG were added to the excised gel slice containing the DNA of interest. The resulting mixture was incubated at 50 °C until the gel was completely dissolved. Then 1 gel volume of isopropanol was added and the resulting solution was mixed by vortexing. Afterwards the solution was applied to a QIAquick spin column in a 2.0 ml collection tube. In order to bind DNA to the silica membrane of the spin column the mixture was centrifuged for 1 min. at 13,000 rpm. After removing the flow-through, bound DNA was washed with 750 µl of Buffer PE and centrifuged again for 1 min. at 13,000 rpm. Then the QIAquick spin column was placed into a fresh 1.5 ml tube and DNA was eluted by adding 30 µl of distilled water to the center of the silica gel membrane and further centrifugation for 1 min. at 13,000 rpm.

Ligation of DNA into pCR® II TOPO® vector

Purified PCR products were subcloned into the pCR® II TOPO® vector according to the protocol of the TOPO TA cloning® kit from Invitrogen.

- 2.0 µl.....DNA (PCR product)
- 1.0 µl.....Salt solution
- 2.0 µl.....Water (aqua dest.)
- 1.0 µl.....pCR II TOPO vector

Both, TOPO vector and salt solution were components of the cloning kit. Incubation time of the ligation mix was up to 30 min. 2 µl of the ligation mix were used for transformation of *E.coli* DH5α.

Transformation of *E.coli* DH5α

For transformation One Shot® MAX Efficiency® DH5 α™ Chemically Competent Cells (cat.no.12297-016) purchased from Invitrogen were used. After the cells were put on ice, 2-6 µl of the ligation reaction were added. The cells were incubated on ice for 30 min. before a heat shock of 30 sec. at 42°C was executed. In the next step 250 µl of SOC-medium (pre warmed at 37°C) were added to the cells and the resulting mixture was shaken at 37°C and 225 rpm for 1 h. Afterwards, the mixture was plated onto LB-plates supplemented with kanamycin. The plates were incubated at 37°C overnight. Next day single colonies were picked from the plates by pipette tips and overnight cultures were started by placing the tips into tubes containing 4.0 ml LB-medium and adding kanamycin (30 mg/ml) at a ratio of 1:1000 (final concentration of kanamycin:30 µg/ml). Isolation of plasmids carrying the gene of interest was done according the plasmid miniprep protocol as described above.

Restriction digestion of TOPO vectors

DNA ligated into pCR® II TOPO® vector was supposed to contain the recognition sites for endonucleases XhoI (CTCGAG) and SalI (GTCGAC) on the 5`end and the 3`end respectively. In order to cut the DNA of interest out of the TOPO vector a restriction digest using the endonucleases XhoI and SalI was performed. The restriction endonucleases were meant to create sticky ends for ligation into the vector pIRES2-EGFP. The composition of the reaction mix was as follows:

- 30.0 µl.....DNA
- 1.0 µl.....RNase
- 1.5 µl.....XhoI
- 1.5 µl.....SalI
- 0.5 µl.....BSA (at a ratio of 1:100 to the total volume)
- 5.0 µl.....10 x buffer (NEBuffer 2; at a ratio of 1:10 to the total volume)
- 10.5 µl.....water (aqua dest.)

All reagents used for digestion were purchased from New England BioLabs Inc. The digestion was carried out for at least 3 h up to 16 h. Before the reaction mix was applied to the 1% agarose gel containing ethidium bromide, 5.0 µl of loading dye were added.

The expected 1.3kb products were extracted and purified according to the protocol of QIAquick® PCR Purification Kit from QIAGEN (cat. no. 28104).

Ligation of DNA into pIRES2-EGFP and transformation of *E.coli* DH5α

HOXA3 DNA possessing sticky ends created by restriction digestion with the restriction endonucleases XhoI and SalI had to be cloned into the multiple cloning site of the expression vector pIRES2-EGFP (Clontech Laboratories Inc., CA, USA, discontinued). In order to ensure ligation, the expression vector needed to have sticky ends compatible to those of the HOXA3 insert. Thus the empty vector had to be treated with the same restriction endonucleases as the HOXA3 gene. Ligation of the coding sequence of HOXA3 into pIRES2-EGFP was catalysed by T4 DNA-ligase (Invitrogen). The ligation reaction mix was composed of:

- 6.0 µl.....HOXA3 DNA
- 2.0 µl.....pIRES2-EGFP
- 1.0 µl.....10 x ligase buffer
- 1.0 µl.....T4 DNA-Ligase

Ligation was executed at 16 °C overnight. Transformation of *E.coli* DH5α was done with 5 µl of ligated DNA as described above.

Capillary sequencing

Capillary sequencing was performed in order to control, whether pIRES2-EGFP was carrying the coding sequence of the HOXA3 gene. First, cycle sequencing reactions were executed to generate ddNTP labelled DNA fragments which could be detected afterwards by the ABI Prism 377 sequencing detection system. Primers used for the cycle sequencing reaction were pIRES sequencing forward and reverse primer purchased from Invitrogen. The composition of the cycle sequencing reaction mix was as follows:

- 5.0 µl.....Water (aqua dest.)
- 2.0 µl.....Primer (pIRES sequencing forward **or** reverse primer)
- 2.0 µl.....Big Dye TM Reaction Mix (Applied Biosystems)
- 1.0 µl.....DNA

For each sample that had to be sequenced two cycle sequencing reaction mixes were prepared which differed in added primers. One mix contained pIRES sequencing forward primer whereas the other cycle sequencing reaction mix contained pIRES sequencing reverse primer. DNA polymerase needed for primer extension as well as ddNTPs were contained in the added Big Dye TM Reaction Mix.

Cycle sequencing reaction program:

96°C	1 min.		
96°C	12 sec.	}	29 cycles
56°C	7 sec.		
60°C	2 min.		
4°C	forever		

After finishing the cycle sequencing reaction unincorporated ddNTPs were removed from the reaction mix by using the DyeEx 2.0 Spin Kit (cat. no. 63206) purchased from QIAGEN. Columns filled with Sephadex G50 were used to remove unbound ddNTPs. DNA fragments labelled with ddNTPs were eluted in 20 µl of water. Before sequencing was finally started 20 µl of formamide were added to the samples.

Endotoxin free plasmid midipreparation

Endotoxin free plasmid midipreparation was executed using the QIAfilterTM Midi Kit (25) from QIAGEN (cat. no. 1224). Initially, 5 µl of the glycerol stock of transformed bacterial cells were added to 50 ml LB medium supplemented with 50 µl kanamycin. The resulting mixture was incubated on a shaker at 37°C and 225 rpm overnight. The next day, the bacterial cell suspension was centrifuged for 20 min. at 6000 x g at 4°C and the resulting bacterial cell pellet was dissolved in 4 ml of RNase A-containing buffer P1. After addition of lysis buffer P2 and an incubation time of 5 min., neutralization buffer P3 was added. The resulting mixture was poured into the barrel of a QIAfilter Cartridge and after 10 min. of incubation the cell lysate was filtered into a 50 ml Falcon tube. In the next step, 1ml buffer ER was added to

the filtered lysate and after 30 min. of incubation on ice, the lysate was applied to an equilibrated QIAGEN tip where the plasmid DNA was expected to bind to anion-exchange resin. The QIAGEN tip was then washed twice with 10 ml buffer QC. Elution of plasmid DNA was executed with 5 ml of buffer QN. The eluted DNA was collected in a 10 ml endotoxin free polyallomer tube. After addition of 3.5 ml room-temperature isopropanol to the eluate in order to achieve precipitation of plasmid DNA, the mixture was centrifuged for 30 min. at 15,000 x g and 4°C. The resulting DNA pellet was washed with 2 ml of endotoxin free room-temperature 70% ethanol. After further centrifugation for 10 min. at 15,000 x g followed by removal of the supernatant, DNA was dissolved in 100 µl of endotoxin free water. Finally, DNA concentration was measured as described below. Endotoxin free DNA obtained from endotoxin free plasmid midiprep was used for transfection of iHUVES in order to study transient overexpression of the HOXA3 gene in an endothelial cell line.

Spectrophotometric measurement of DNA concentration

A U-2000 Spectrophotometer (Hitachi) was used to determine DNA concentration of a sample by measuring the optical density (absorbance) at 260 nm. Before measurement, dilution of the sample was executed at a ratio of 1:200 by adding 3 µl of the sample to 600 µl of DNase free water.

The measured absorbance was used to determine DNA concentration according to the formula:

$$c [\mu\text{g/ml}] = \text{OD}_{260} \times D \times F$$

cConcentration of DNA (µg/ml)

OD₂₆₀Absorbance (optical density) at 260 nm

DDilution used

FStrandedness of DNA (50 for dsDNA)

Measurement of DNA concentration was executed in order to use appropriate amounts of endotoxin free DNA for transfection of iHUVES.

Total RNA isolation from transfected cells

Cells successfully transfected with pIRES2-EGFP carrying the gene of interest were centrifuged for 2 min. at 2,800 rpm and 4 °C. The cell pellet was then dissolved in 1ml of RLT buffer supplemented with 1% β-mercaptoethanol. In preparation for total RNA isolation, the mixture was applied to QIAshredder™ (50) from QIAGEN (cat. no. 79654) in order to

homogenize the cell lysate by centrifugation for 2 min. at 13,000 rpm. Total RNA isolation was executed using the RNeasy[®] Mini Kit (50) from QIAGEN (cat. no. 74104). In the beginning, 350 µl of RNase-free 70 % ethanol were added to the homogenized sample and the resulting mixture was applied to an RNeasy spin column. The loaded RNeasy spin column was centrifuged for 2 min. at 13,000 rpm in order to achieve binding of total RNA to the silica gel membrane. Buffer RW1 was used to wash RNA bound to the silica gel membrane and to remove unwanted excess material. Degradation of unwanted genomic DNA was accomplished by incubation of the silica gel membrane with DNase I diluted with buffer RDD at a ratio of 1:8. Two further washing steps were carried out using buffer RPE before 30 µl of RNase-free water were added to elute RNA.

Reverse transcription

Reverse transcription of total RNA isolated from successfully transfected iHUVESCs was carried out in order to produce cDNA that was applied to TaqMan Low Density Custom Arrays for high throughput real time PCR.

For reverse transcription 20 µl of total RNA were added to Sprint[™] PowerScript[™] PrePrimed Single Shots (Clontech) containing lyophilized master mix composed of reverse transcriptase, random hexamer or oligo(dT)₁₈ primers (20 µM), BSA (10mg/ml), DTT (1M), dNTP mix (10mM each), 10x reaction buffer, cryoprotectant and stabilizers. Reverse transcription was carried out using GeneAmp PCR System 9600.

The thermal cycler program for reverse transcription was as follows:

42 °C	90 min.	} 1 cycle
70 °C	10 min.	
4 °C	forever	

Multiplex PCR

Multiplex PCR was executed in order to control the quality and integrity of cDNAs produced by reverse transcription. The four housekeeping genes BCR, β2-microglobulin, ABL and PBGD were chosen for amplification. Multiplex PCR was carried out using AmpliTaq Gold[®], 5 x 1000 U, with GeneAmp[®] 10X PCR Gold Buffer and MgCl₂ Solution from Applied Biosystems (cat. no. 4311818). Furthermore, GeneAmp dNTPs, also purchased from Applied Biosystems, (cat. no. N808-0007) were added to the PCR reaction mix. Primer pairs for the four housekeeping genes were mixed together and diluted at a ratio of 1:10.

The multiplex PCR reaction mix was composed of as follows:

- 32.75 µl.....Water (aqua dest.)
- 5.0 µl.....10X PCR Gold Buffer
- 3.0 µl.....MgCl₂ Solution (1.5 mM)
- 4.0 µl.....dNTPs (final concentration 200 µM)
- 3.0 µl.....Rapid load
- 0.25 µl.....AmpliTaq Gold[®] (1.25 Units)
- 1.0 µl.....Primer (from 1:10 dilution, final concentration: 2 µM)
- 1.0 µl.....cDNA

The thermal cycler program for multiplex PCR was as follows:

95°C	5 min.	
95°C	1 min.	} 40 cycles
56°C	1 min.	
72°C	90 sec.	
4°C	forever	

GeneAmp PCR System 9600 was used in order to perform multiplex PCR. The sample was applied to a 2% agarose gel containing ethidium bromide and the PCR products were separated according to their length (BCR: 377 bp, β2-microglobulin: 287 bp, ABL: 193 bp, PBGD: 128 bp) by agarose gel electrophoresis.

High throughput real time PCR

The aim of high throughput real time PCR was to investigate the effects of overexpression of the HOXA3 gene on the expression of 125 candidate genes relevant to diabetic microangiopathy. TaqMan[®] Low Density Custom Arrays (Applied Biosystems) were constructed in order to enable 128 simultaneous quantitative real time PCR reactions. More precisely, 128 candidate gene specific primers and probes were spotted onto a total of two micro-fluidic cards referred to as DMA1 and DMA2. Each of these 384-well micro-fluidic cards contained two series of 64 pre-made assays that were applied in triplicates. GAPDH specific primers and probes were located on both TaqMan[®] Low Density Custom Arrays. In addition, DMA2 contained assays for the housekeeping genes NARS and TARDBP which

were not part of the candidate gene set but were chosen for normalization as described below. Thus, both TaqMan[®] Low Density Custom Arrays comprised a total of 128 pre-made assays (Table 1).

For quantitative real time PCR 100 µl of a reaction mix composed of 20 µl cDNA, 405 µl water (Aqua dest.) and 425 µl 2 x TaqMan Universal PCR Master Mix were applied to 4 from 8 loading ports of DMA1 and DMA2 respectively. Subsequent centrifugation of the micro-fluidic cards at 330 g for 2 min. was executed in order to achieve migration of the samples into the wells. Finally, high throughput PCR was carried out using the ABI Prism 7700 sequence detection system (Applied Biosystems).

Table 1. List of candidate genes that were represented in the form of pre-made assays spotted on TaqMan[®] Low Density Custom Arrays.

Number	Gene symbol	Number	Gene symbol	Number	Gene symbol	Number	Gene symbol
1	ABL2	33	EBF	65	MAP4	97	PTK2
2	ACE	34	EGF	66	MAPK11	98	PXN

GAPDH specific primers and probes were found on DMA1 as well as DMA2. Housekeeping genes NARS and TARDBP were chosen for normalization.

4.4 Bioinformatics

Analysis of data obtained from high throughput real time PCR

Thresholds were set manually within regions of linear increase of sigmoid curves generated by analysis of high throughput real time PCR with SDS 2.2 software (Applied Biosystems). Finally, data were exported and calculation of the fold change was done using the $\Delta\Delta C_t$ method. In the beginning, C_t values of the sample were normalized to C_t values of GAPDH, in order to compensate differences in measurements of the sample between DMA1 and DMA2. C_t values normalized to those of GAPDH were then normalized to C_t values of two housekeeping genes (NARS and TARDBP) in order to be able to compare overexpression experiments carried out with different genes. Finally, C_t values of the sample were compared to those of the calibrator sample obtained by transfection of iHUVCEs with the empty vector. Building the difference between the sample to be measured and the calibrator sample allowed for determining the fold change ratio.

Construction of a gene network relevant to diabetic microangiopathy

The fold change ratio (FC) was determined according to the formula:

$$FC = 2^{-\Delta C_t} = x_{ij}/x_i^0$$

x_i^0 ...gene expression of the i-th gene

x_{ij} ...gene expression of the i-th gene when the j-th gene is perturbed

Next, the influence matrix (D) was built in order to describe the effect of perturbation of gene j on the expression of gene i:

$$D_{ij} = \ln (x_{ij}/x_i^0)$$

Building of D was expected to yield one of the three possible results:

$$D_{ij} = \begin{cases} > 0 & \dots \text{perturbation of gene j leads to overexpression of gene i} \\ < 0 & \dots \text{perturbation of gene j leads to downregulation of gene i} \\ = 0 & \dots \text{perturbation of gene j has no effect on the expression of gene i} \end{cases}$$

The next step was carried out according to following consideration: In a given gene network represented by the adjacency matrix (A) it was necessary to find all the direct and indirect regulatory links between gene i and gene j. The connection between the influence matrix (D) and adjacency matrix (A) is given with the following equation:

$$A_{ji} = \ln (D+I), \text{ where } \ln(D+I) \text{ is a matrix logarithm.}$$

Finally, a threshold was set, corresponding to in advance given network connectivity, to select significant link weights. The non-significant ones, below the threshold, were set to zero.

4.5 Cell biology methods

Cells

Immortalized human umbilical vein endothelial cells (iHUEVCs) were a kind gift from Professor Miertinnen (University of Helsinki, Finland). These cells were immortalized with the human telomerase catalytic protein (hTERT). Immortalized human umbilical vein endothelial cells have previously been shown to largely maintain their endothelial character, a property necessary for the studies of diabetic microangiopathy. Another reason for choosing iHUEVCs was technical feasibility including a reasonable transfection efficiency (30-75 % with pIRES2-EGFP) that would be important for later transfection studies. Cells were maintained in RPMI 1640 medium (GIBCO, cat. no. 51800-035) supplemented with 10 % FBS (fetal bovine serum, GIBCO, cat. no.10108-157) and 1% penicillin/streptomycin (GIBCO, cat. no.15140-122). Incubation of iHUEVCs was carried out at 37 °C in an incubator with a CO₂ content of 5 % and 90 % relative humidity.

Transfections

Transfection was carried out when iHUEVCs maintained in in RPMI 1640 medium (GIBCO, cat. no. 51800-035) supplemented with 10 % FBS (fetal bovine serum, GIBCO, cat. no.10108-157) and 1% penicillin/streptomycin (GIBCO, cat. no.15140-122) were grown to 90-95% confluence. The amount of endotoxin free plasmid DNA, Lipofectamine2000TM (Invitrogen, cat. no. 11668-027) and OptiMEM[®] (Invitrogen) used for successful transfection was adapted according to the effective growth area of the culture dishes where the cells were grown. At the beginning, endotoxin free plasmid DNA (0.4 µg/cm²) and the cationic lipid-based reagent Lipofectamine2000TM (0.5 µl/cm²) were separately incubated in tubes containing OptiMEM[®] (25 µl/ cm²) for 5 min. at room temperature. Prior to transfection, the contents of both tubes were combined and incubated at least for further 20 min. at room temperature. The transfection mix was then added to the grown cells and after 2-4 h of incubation at 37°C the mixture was removed and RPMI 1640 medium supplemented with 10 % FBS (fetal bovine serum) and 1% penicillin/streptomycin was added to the cells. After 24 h of incubation at 37°C fluorescence microscopy was used to identify iHUEVCs that were successfully transfected with pIRES2-EGFP carrying the gene of interest. According to the

manufacturer the EGFP encoded by the plasmid was expected to have its excitation maximum at 488 nm and its emission maximum at 507 nm.

Flow cytometry

Flow cytometry was carried out by the Division of Rheumatology/Department of Internal Medicine III in cooperation with the Core Unit Cell Sorting, both from the Medical University of Vienna. Flow cytometric cell sorting was performed in order to isolate and quantify successfully transfected cells. Cells were harvested 48 h after transfection by addition of 1x trypsin/EDTA and immediate centrifugation for 4 min. at 1800 rpm. The resulting pellet was resuspended in 1 ml of RPMI 1640 medium supplemented with 10 % FBS (fetal bovine serum) and 1% penicillin/streptomycin and 7-amino-actinomycin D (7-AAD, Fluka, Buchs SG, Switzerland, cat. no. 06648) was added at 1 µg/ml. Flow cytometric cell sorting was then carried out using a BD FACSAria™ flow cytometer, EGFP emission being detected via FL1 channel using a bandpass filter at 530±15nm. Sort criteria combined a generously wide scatterlight region excluding small particles (cell fragments and debris) with positivity for EGFP as well as negativity for 7-AAD. Furthermore, transfection efficiencies and EGFP half-life were determined using a BD FACSCalibur™ flow cytometer. The sorted EGFP-positive, 7-AAD negative cells were lysed in 350µl of RLT buffer supplemented with 1% β-mercaptoethanol and stored at -80°C until RNA isolation was executed. For isolation of sufficient RNA, the sorting had to yield at least 300,000 EGFP-positive cells.

Immunofluorescence staining of HOXA3 proteins

The purpose of immunofluorescence staining was to analyze the distribution of the HOXA3 protein in the cell under several conditions including transient expression of the protein to be analyzed, overexpression of another protein or normal conditions. Prior to immune fluorescence staining iHUVES maintained RPMI 1640 medium supplemented with 10 % FBS (fetal bovine serum) and 1% penicillin/streptomycin were grown in 9.6 cm² petri dishes. On the day of staining the medium was removed and the cells were fixed in 4% PFA in PBS for a minimum of 10 min at room temperature. After removal of 4% PFA/PBS the cells were washed three times with PBS and 0.1% Triton-X-100 in PBS was added for permeabilization of the cell membrane. After 10 min. of incubation at room temperature Triton-X-100 was removed and 200 µl of goat serum diluted in PBS at a ratio of 1:10 were added to each 9.6 cm² dish for 20 min. in order to block unspecific binding sites. Prior to use, the primary antibody (Anti-HOXA3) was diluted in PBS at a ratio of 1:100. The antibody of choice

against HOXA3 was the unconjugated polyclonal antibody anti-homeobox protein Hox-A3 (AVIVA SYSTEMS BIOLOGY; cat. no. ARP36056_T200) produced in rabbits. Anti-Hoxa3 was delivered in a state lyophilised from PBS buffer with 2% sucrose. After addition of 100 μ l distilled water the final antibody concentration was 2 mg/ml.

The primary antibody was added to the cells for 45 min. at room temperature. Afterwards, the cells were washed with PBS before the secondary antibody diluted in PBS at a ratio of 1:1000 was added. In case of rabbit anti-human HOXA3 polyclonal antibody serving as primary antibody, the secondary antibody of choice was Alexa Fluor 594 goat anti-rabbit antibody (MolecularProbes) labelled with red-fluorescent dye. The secondary antibody was added for 45 min. at room-temperature. After washing with PBS, DAPI-staining (1:50,000) was executed for 1 min. in order to visualize cell nuclei. After the final wash step with PBS, cells were covered with GelTol mounting medium (Thermo Electron Corporation, PA, USA, cat. no. 484950) and a cover glass. Analysis of immunostained cells was performed under the microscope. AxioCam (ZEISS, Germany) was used for taking pictures of the cells.

4.6 Protein chemistry methods

Protein assay in Laemmli buffer

This method was executed according to the article of Karlsson et al. (1994) in order to determine protein concentrations within cell samples. At the beginning, cell samples were solubilized in Laemmli buffer and heated at 96°C for 3 min. before centrifugation at 10,000 x g for 5 min. was performed. Next, 9 μ l aliquots of the samples were applied to a microtiter plate and diluted at a ratio of 1:10 by addition of 81 μ l of Laemmli buffer.

Different concentrations (500 μ g/ml, 250 μ g/ml, 100 μ g/ml, 50 μ g/ml, 25 μ g/ml and 10 μ g/ml) of bovine serum albumin (BSA) solubilized in Laemmli buffer were prepared in order to determine protein concentrations of the samples by a BSA standard curve. Then, 90 μ l of the respective BSA solutions were also applied to the microtiter plate.

Finally, 60 μ l of 60% TCA were added to the samples and the BSA solutions and the yellow turned mixtures were incubated for 10-30 min. at room temperature.

Microplate reader Synergy-HT (BIO-TEK) was used for measuring turbidity of the samples and the BSA-solutions at 570 nm. Furthermore, a BSA standard curve was built in order to determine protein concentrations (μ g/ml). In order to obtain correct protein concentrations it was necessary to take the dilution of the samples (1:10) into account.

Western blot analysis

Western blots of transfected and nontransfected iHUECs were probed for HOXA3. Western blot analysis of HOXA3 protein was done for CFL1, CASP3 and HOXA3 transfected iHUECs as well as for nontransfected cells. At the beginning 20µg of total protein isolated from transfected and nontransfected cells were applied to SDS-PAGE carried out at 120V. The running gel used for separation of proteins contained 12% acrylamide. Transfer of proteins to nitrocellulose membranes was carried out at 20V overnight. After transfer, the nitrocellulose membrane was stained with Ponceau S red in order to visualize proteins. The membrane was then blocked with 5% milk powder in 1xTBST for at least 20 min. The primary antibody was added at room temperature for 1 h. The antibody of choice against HOXA3 was Mouse Anti-Human HOXA3 Polyclonal Antibody, Unconjugated from ABR-Affinity BioReagents (cat. no. PA1-52660). Prior to use, anti-HOXA3 was diluted at a ratio of 1:1000 in 2.5% milk powder in 1xTBST. After 1 h of incubation with the primary antibody the membrane was washed three times for 5 min. each with 1xTBST. The secondary antibody (HRP rabbit anti-mouse) diluted at a ratio of 1:4000 in 2.5% milk powder in 1xTBST was then added to the blots at room temperature for at least 1 h. Afterwards, several washing steps using TBST were carried out for 50 min. Finally, ECL plus™ Western Blotting Detection Reagent (Amersham Biosciences) was added to the blot prior to detection of HOXA3 by chemiluminescence using Lumi-Imager F1™ (Rocher). Analysis of images acquired by Lumi-Imager F1™ was carried out using LumiAnalyst™ software (Rocher).

5 Results

5.1 Flow cytometry

Separation and counting of iHUECs successfully transfected with the cloned coding sequence of HOXA3 were executed by flow cytometric cell sorting. Thereby, we collected of a total number of 307,423 intact, viable EGFP-positive cells for subsequent isolation of total RNA.

5.2 RNA-isolation and Multiplex PCR

Total RNA isolated from iHUECs transiently expressing HOXA3 was reverse- transcribed in order to obtain cDNA that could be applied to quantitative real time PCR. Before cDNA was loaded onto TaqMan[®] Low Density Custom Arrays, multiplex PCR of four housekeeping genes (BCR, β 2-microglobulin, ABL and PBGD) was performed, providing information about quality and integrity of cDNAs produced by reverse transcription. Multiplex PCR products separated on a 2 % agarose gel yielded four bands of different size (Figure 6). In order to exclude technical failures concerning the method, multiplex PCR was carried out for a control sample as well (data not shown).

Figure 6. Control of quality and integrity of cDNA sample

Multiplex PCR of the four housekeeping genes (BCR, β 2-microglobulin, ABL and PBGD) and subsequent separation of the PCR products by 2 % agarose gel electrophoresis yielded four bands (lane 2) of different size (BCR: 377 bp, β 2-microglobulin: 287 bp, ABL: 193 bp, PBGD: 128 bp). The 100 bp ladder (lanes 1 and 3) was used as size marker.

5.3 Quantitative real time PCR

5.3.1 Determination of fold change and correlation in expression patterns

The aim of high throughput real time PCR was to investigate the effects of transient expression of the HOXA3 gene on the expression of the 125 candidate genes relevant to diabetic microangiopathy. Therefore, cDNA obtained from reverse transcription of total RNA isolated from iHUEVCs transiently expressing HOXA3 was loaded onto two TaqMan® Low Density Custom Arrays (referred to as DMA1 and DMA2). A total of 128 pre-made assays were spotted on both micro-fluidic cards enabling 128 simultaneous quantitative real time PCR reactions (as already described in Materials and Methods sections).

Analysis of quantitative real time PCR with SDS 2.2 software generated sigmoid curves representing the increase of the respective PCR products. In order to obtain precise C_t values, thresholds were set manually within regions of linear increase of these curves. After normalization of C_t values to these of GAPDH, the two housekeeping genes NARS and TARDBP and the calibrator sample, the fold change was determined according to the formula:

$$FC = 2^{-\Delta C_t} = x_{ij}/x_i^0$$

Software developed within our group (Stokic et al., 2008) was able to create four different profiles for analysis of functional interactions between members of the candidate gene set as well as correlations in expression patterns. On the one hand, this software was used to generate global profiles of both, expression and correlation, but on the other hand profiles of single gene expression and correlation were created.

Global profiles of correlation allowed for analysis of correlation between transiently expressed genes concerning their effects on the expression of the candidate gene set.

The global profile of expression was built in order to demonstrate the upregulating and downregulating effects of a transiently expressed gene on candidate gene expression.

The expression pattern of a certain gene within the candidate gene set as a result of the respective experiments of transient gene expression was demonstrated by the single gene expression profile. The single gene profile of correlation allowed for analysis of correlation between all candidate genes within the set concerning their expression as a result of transient gene expression.

In order to obtain reliable results, three replicates of transient expression of HOXA3 followed by RNA-isolation, cDNA synthesis and quantitative real time PCR were executed. Transfected iHUEVCs of the first trial emerged to be contaminated by mycoplasmas whereas cells used for transfection during the second and the third trials were free from contamination. Since the experimental conditions of the third trial of transient expression of HOXA3 were most favourable, data obtained from this trial were considered to be significant for examination of the role of HOXA3 in a gene network relevant to diabetic microangiopathy.

1) The **global profile of correlation** was used to compare the respective effect on the candidate gene set of every transiently expressed gene to the effect of transient expression of HOXA3 on candidate gene expression (Figure 7). More precisely, the global profile of correlation built for HOXA3 allowed for analysis of correlation between transiently expressed HOXA3 and the other overexpressed genes in terms of their effects on candidate gene expression. Values close to +1 indicated a high degree of correlation whereas values close to 0 reflected poor correlation. Table 2 outlines correlations that emerged between transient HOXA3 expression and overexpression of 44 genes concerning the influence on the candidate gene set.

Concerning the effect on the candidate gene set, HOXA3-new was found to show highest correlation with overexpression of RPIB1 (correlation value: 0.864). The RPIB1 gene encodes ribose-5-phosphate isomerase, an enzyme that converts ribulose 5-phosphate to ribose-5-phosphate in the pentose phosphate pathway (Huck et al., 2004).

Furthermore, transient expression of the gene encoding the intercellular adhesion molecule ICAM1 showed high correlation with transiently expressed HOXA3-new in terms of the effects on the expression of the candidate gene set (correlation value: 0.738).

Comparison of the three trials of transient expression of HOXA3 with respect to the influence on the expression pattern of the candidate genes delivered interesting results. Correlation found between transiently expressed HOXA3 of the second (HOXA3-2.Versuch) and the third (HOXA3-new) trial accounted for almost 72% (correlation value: 0.717). Both trials of transient HOXA3 expression were carried out under similar conditions using iHUEVCs free from any contamination. Nevertheless, small differences concerning the effects on candidate gene expression between HOXA3-2.versuch and HOXA3- new were detected. This result was acceptable however, since small variations concerning gene expression in iHUEVCs after two trials of transfection with HOXA3 were expected to occur. Comparison of transiently expressed HOXA3 of the first trial (HOXA3-old) to HOXA3-new yielded a significant

difference in terms of the effects on the candidate gene expression. Cells used for transient exogenous expression of HOXA3 in the first trial turned out to be contaminated with mycoplasmas. Correlation found between HOXA3-old and HOXA3-new accounted for 13% (correlation value: 0.131). As expected, this result strongly suggests that mycoplasma contamination has significant influence on the gene expression profile of cells affected.

Concerning the influence on the expression of the candidate gene set, transient expression of two more genes was found to yield a correlation value greater than 0.7 when compared to HOXA3-new. One of them, UGDH (correlation value: 0.707) encodes the enzyme UDP-glucose dehydrogenase that is known to catalyze two oxidations of UDP-glucose to generate UDP-glucuronic acid required for synthesis of extracellular matrix polysaccharides (Sommer et al., 2004). The other one, PLD (correlation value: 0.703) codes for phospholipase D, an enzyme that hydrolyzes phosphatidylcholine to yield the lipid second messenger phosphatidic acid and free choline (Whatmore et al., 1996).

Table 2. Correlations between transient HOXA3 expression and overexpression of 44 genes concerning the effect on the candidate gene set.

Position	Gene symbol	Correlation value	Position	Gene symbol	Correlation value
1	HOXA3-new	1.000	24	TGFb1	0.378
2	RPIB1	0.864	25	CXCL12	0.309

21	GNAS2	0.404	44	ATP6VOD1	-0.030
22	GCA	0.398	45	CASP3	-0.065
23	c-Jun	0.395			

The respective genes involved are listed according to their correlation value, starting with the highest degree of positive correlation. The gene symbols HOXA3-old, HOXA3-2.Versuch and HOXA3-new were used in reference to the first, the second and the third trial respectively of transient HOXA3 expression followed by RNA-isolation, reverse transcription and quantitative real time PCR.

Figure 7. Global profile of correlation built for HOXA3. Values close to +1 indicate a high degree of correlation whereas values close to 0 reflect poor correlation.

2) The **global profile of expression** was used to analyze the upregulating and downregulating effects of transient HOXA3-expression on the expression of the candidate gene set (Figure 8). The magnitude of change in candidate gene expression as a result of HOXA3 overexpression was displayed by determination of the fold change. Table 3 summarizes the most upregulated as well as the most downregulated candidate genes as a result of transient expression of HOXA3.

Transient expression of HOXA3 was found to result in almost 44600 fold elevated levels of HOXA3 transcripts.

The majority of genes notably upregulated upon transient HOXA3 expression were found to encode proteins acting in adipocytes or being involved in reorganization of the actin cytoskeleton.

Overexpression of HOXA3 resulted in enormously increased expression of the EBF gene encoding the early B-cell factor. Early B-cell factor is a DNA binding protein that activates transcription of several B-cell specific genes and plays a critical role in early B-cell development (Hagman et al., 1991). Furthermore, the EBF gene product was found to act as transcription factor in olfactory neurons (Kudrycki et al., 1993). The EBF gene was also shown to be expressed during adipogenesis, a process by which adipocytes are formed (Jimenez et al., 2007).

Expression of sorbin and SH3-domain-containing-1 (SORBS1) gene known to participate in insulin signaling in adipocytes and thereby playing a critical role in the regulation of glucose uptake (Baumann et al., 2000) was elevated as a result of HOXA3 overexpression. According to previous studies, defects in SORBS1 may play a critical role in the pathology of human disorders with insulin resistance including the development of obesity and type 2 diabetes (Lin et al., 2001).

The RHOJ gene encoding a member of the family of small Rho GTPases was upregulated upon transient HOXA3 expression. Rho GTPases are known to affect actin cytoskeleton reorganization by regulation of actin dynamics. Proteins of the Rho family of small GTPases switch between an active GTP-bound and an inactive GDP-bound state (Vignal et al., 2003). The Rho GTPase encoded by the RHOJ gene has been found to act as an essential regulator of the early endocytic pathway (de Toledo et. al, 2003). Furthermore, RHOJ plays a critical role in early adipocyte differentiation (Nishizuka et al., 2003).

Overexpression of HOXA3 was found to result in elevated expression of the EPHA4 gene encoding the EPHA4 receptor that belongs to the Eph family of receptor tyrosine kinases. Eph receptors and their ligands, the ephrins are known to act in the developing and the mature

nervous system (Kullander and Klein, 2002) by reorganization of the actin cytoskeleton leading to modification of cell shape and movement (Henkemeyer et al., 2003). The EPHA4 receptor has been shown to affect β_1 -integrin signaling pathways in neuronal cells by inhibiting β_1 -integrin activity (Bourgin et al., 2008).

The expression of the NOS3 gene coding for endothelial nitric oxide synthase was found to be upregulated as a result of transient HOXA3 expression. Nitric oxide synthases are known to catalyze the synthesis of nitric oxide (NO). Formation of nitric oxide results in its diffusion into the smooth muscle where it activates soluble guanylate cyclase (sGC), an enzyme catalyzing the synthesis of 3', 5'- cyclic guanosine monophosphate (cGMP) leading to smooth muscle relaxation and vasodilation. Nitric oxide derived from NOS3 is thought to be the most important regulator of the vascular tone (Alderton, Cooper and Knowles, 2001).

Transient expression of HOXA3 resulted in elevated expression of the IL-8 gene encoding the chemokine interleukin 8. Furthermore, the expression of the gene coding for gap junction protein alpha 1 (GJA1) was upregulated as a result of HOXA3 overexpression.

Among the candidate genes notably downregulated upon transient HOXA3 expression the encoded proteins differ to a great extent in terms of function.

The ITGA1 gene encoding the integrin alpha subunit and the gene Parkinson disease (autosomal recessive, early onset) 7, also known as PARK7 were downregulated as a consequence of HOXA3 overexpression.

Overexpression of HOXA3 was found to result in downregulated expression of the VEGF gene coding for the vascular endothelial growth factor. Members of the VEGF gene family including VEGF have been shown to be critical for growth and differentiation of vascular as well as lymphatic endothelial cells (Korpelainen and Alitalo, 1998). VEGF has been found to play a crucial role in the early development of the vasculature. Furthermore, VEGF is considered to be the major regulator of angiogenesis (Leung et al., 1989).

Downregulated expression of the PHGDH gene encoding the enzyme 3-phosphoglycerate dehydrogenase was found to occur as a result of transient HOXA3 expression. The PHGDH gene product catalyzes the conversion of 3-phosphoglycerate into 3-phosphohydroxypyruvate during L-serine biosynthesis (Snell, 1986). L-serine is an important precursor for the synthesis of proteins, membrane lipids, glycine and D-serine (Snell, 1984). PHGDH deficiency is associated with defective L-serine biosynthesis. Furthermore, it has been found that the PHGDH gene product and L-serine are crucial for metabolism, development and function of the central nervous system (Klomp et al., 2000).

The expression of the GAPDH gene encoding the glycolytic enzyme glyceraldehyde-3-phosphate dehydrogenase was downregulated upon overexpression of HOXA3. The GAPDH protein catalyzes the conversion of glyceraldehyde-3-phosphate into 1, 3-diphosphoglycerate. Overproduction of superoxide O_2^- induced by hyperglycaemia has been shown to result in activation of the enzyme poly (ADP-ribose) polymerase (PARP) which in turn inhibits the enzyme GAPDH by poly-ADP ribosylation resulting in accumulation of glycolytic metabolites upstream of GAPDH leading to activation of the four biochemical pathways that are known to contribute to hyperglycaemia-induced damage (Du et al., 2003).

The family of FBXO genes encode proteins, all of them possessing a protein motif also referred to as the F-box. F-box proteins are known to be components of the SCF ubiquitin-ligase complexes. The function of F-box proteins within these complexes is to provide a site for protein-protein interaction via their F-box motifs (Kipreos and Pagano, 2000). Upon transient expression of HOXA3, the expression of the FBXO7 gene was found to be downregulated.

The C1s gene encodes a serine protease that is known to be a subunit of the multimeric C1 protein complex of the complement system (Arlaud, Colomb and Gagnon, 1987). C1s cleaves and activates C4 and C2 resulting in formation of the C3 convertase (Schumaker, Zavodszky and Poon, 1987). Downregulated expression of the C1s gene was found to be the consequence of HOXA3 overexpression.

Another gene notably downregulated upon transient expression of HOXA3 was the GCA gene encoding the Ca^{2+} binding protein grancalcin found in neutrophils, monocytes and lymphocytes (Boyhan et al., 1991).

Table 3. List of the most upregulated and the most downregulated candidate genes upon transient HOXA3 expression.

Gene symbol	Fold change	upregulation or downregulation	Gene symbol	Fold change	upregulation or downregulation
EBF	4.86812E+12	upregulation	GAPDH	0.005	downregulation
HOXA3	44566.06	upregulation	ITGA1	0.052	downregulation
SORBS1	18.89	upregulation	PARK7	0.098	downregulation
RHOJ	15.49	upregulation	VEGF	0.098	downregulation
EPHA4	14.01	upregulation	PHGDH	0.123	downregulation
GJA1	13.53	upregulation	FBXO7	0.145	downregulation
IL-8	13.08	upregulation	C1S	0.160	downregulation
NOS3	10.81	upregulation	GCA	0.222	downregulation

The fold change was determined in order to analyze the magnitude of change in candidate gene expression as a result of transient HOXA3 expression.

Figure 8. Global profile of expression built for HOXA3. Determination of the fold change was executed in order to display the magnitude of change in candidate gene expression as a result of HOXA3 overexpression. A fold change greater than 1 indicates upregulated candidate gene expression. Downregulated candidate gene expression is indicated by a fold change smaller than 1.

3) The **single gene** profile of **expression** of HOXA3 was built in order to analyze the effects of transient expression of the candidate genes including HOXA3 on the expression pattern of HOXA3 within the candidate gene set (Figure 9). Changes in HOXA3 expression as a result of overexpression of the respective candidate genes were displayed by determination of the fold change. Table 4 lists the candidate genes that were found to have the most significant influence upon transient expression on the expression pattern of HOXA3.

As previously described, transient expression of HOXA3 was found to result in elevated transcription of HOXA3.

Transient expression of CFL1 encoding the protein cofilin1 resulted in enormously increased expression of endogenous HOXA3. Cofilin1 belongs to the family of actin depolymerising factor (ADF)/cofilins. Members of this family are actin binding proteins that are known to promote depolymerization of actin filaments, thereby playing a critical role in cytokinesis, cell motility and morphogenesis in mammals. The proteins cofilin1 and ADF are coexpressed in nonmuscle cells where they contribute to cytoskeletal dynamics with overlapping functions (Hotulainen et al., 2005).

Endogenous HOXA3 expression was elevated as a result of transient KLF6 expression. The protein encoded by KLF6 is the Krüppel-like factor 6, a member of the Krüppel-like family of transcription factors. Proteins of this family possess highly conserved carboxy terminal zinc finger domains enabling specific DNA binding to GC rich sites within the promoter region of target genes. The transcription activation domain is located at the amino terminus (Dang, Pevsner and Yang, 2000). KLF6 has been found to act as tumor suppressor gene that is mutated in human prostate cancer (Narla et al., 2001). Furthermore, KLF6 has turned out to promote adipocyte differentiation by inhibition of the proto-oncogene Delta-like1 (DLK1) in preadipocytes (Dan Li et al., 2005).

Another gene found to result in increased expression of endogenous HOXA3 upon transient expression was CXCL12 encoding the chemokine that is also referred to as the stromal cell-derived factor 1. The gene product of CXCL12 has been shown to promote angiogenesis by mediating recruitment and migration of endothelial progenitor cells as well as endothelial cells in response to ischemic injuries. Binding of the CXCL12 protein to the CXCR4-receptor induces the proangiogenic signaling pathway (Askari et al., 2003; Deshane et al., 2007). An angiogenesis promoting activity by induction of endothelial cell migration has been also demonstrated for HOXA3. Studies revealed that constitutive expression of HOXA3 accelerated the healing process of diabetic wounds in mice (Kimberly et al., 2005).

HOXA3 expression was downregulated upon transient expression of CASP3 coding for caspase 3. Caspases are cysteine-aspartyl specific proteases that are known to be crucial for apoptosis (Creagh, Conroy and Martin, 2003). Caspase3 is an effector caspase that has been found to mediate apoptosis of β -cells of the pancreas, a process known to be significant for the occurrence of type 1 diabetes (Liadis et al., 2005).

Downregulated expression of endogenous HOXA3 was found to occur in untransfected cells treated with medium containing high concentrations of D-glucose. Since elevated expression of HOXA3 protein has been found in sera of patients suffering from diabetes mellitus (Wick et al., unpublished data), this result was unexpected.

Transient expression of FZD4 encoding frizzled homolog 4 resulted in downregulated expression of HOXA3. FZD4 belongs to the frizzled gene family whose members are known to code for transmembrane proteins acting as receptors for Wnt ligands (Reya and Clevers, 2005). The gene product encoded by FZD4 has been found to bind the non-Wnt ligand norrin (Nichrs, 2004) that appears to have an angiogenesis promoting activity (Ohlmann et al., 2005). Studies have revealed that mutations in the FZD4 gene result in familial exudative vitreoretinopathy (FEVR), a disorder characterized by defects in retinal vascular development (Robitaille et al., 2002).

Furthermore, downregulated expression of HOXA3 occurred as a result of transient expression of ATP6VOD1, a gene encoding the D1 subunit of the transmembrane VO domain of the enzyme ATPase.

Table 4. List of the candidate genes having the most significant influence upon transient expression on HOXA3 expression within the candidate gene set.

Gene symbol	Fold change	upregulation or downregulation	Gene symbol	Fold change	upregulation or downregulation
HOXA3	44566.06	upregulation	CASP3	0.002	downregulation
CFL1	10177.78	upregulation	D-glucose	0.079	downregulation
KLF6	16.87	upregulation	FZD4	0.188	downregulation
CXCL12	12.36	upregulation	ATP6VOD1	0.374	downregulation

Determination of the fold change was performed in order to indicate the magnitude of change in HOXA3 expression as a result of transient expression of the respective candidate genes including HOXA3. The gene symbol D-glucose refers to untransfected iHUEVCs that were treated with D-glucose.

Figure 9. Single gene profile of expression built for HOXA3. Determination of the fold change was executed in order to display the magnitude of change of HOXA3 RNA expression as a result of transient expression of the respective candidate genes. A fold change greater than 1 indicates upregulated HOXA3 expression. Downregulated HOXA3 expression is indicated by a fold change smaller than 1.

4) The **single gene profile of correlation** built for HOXA3 allowed for analysis of correlation between HOXA3 and all the other candidate genes within the set concerning their expression as a result of transient candidate gene expression (Figure 10). Values close to +1 indicated high correlation in expression. On the other hand values close to 0 indicated poor correlation. Table 5 lists genes that were found to show highest correlation with HOXA3 concerning their expression upon transient expression of the respective candidate genes.

Values found for correlation between HOXA3 and the other candidate genes concerning their expression pattern as a result of transient expression of the respective candidate genes were smaller than 0.5. These data indicate correlation below 50% between HOXA3 and the other genes within the set in terms of expression in response to the overexpression experiments.

The gene SERPINE1 encoding the plasminogen activator inhibitor 1, a serine proteinase inhibitor protein was found to show highest correlation (correlation value: 0.468) with HOXA3 in terms of expression upon overexpression of the respective candidate genes. Plasminogen activator inhibitor 1 (PAI-1) has been found to cause detachment of cells from extracellular matrices by binding to urokinase plasminogen activator (uPA) in complexes mediating attachment of cells to the extracellular matrix. These complexes are composed of uPA, its receptor uPAR and integrins (Czekay et al., 2003). Previous studies have revealed a link between uPAR and HOXA3 since constitutive expression of HOXA3 leads to upregulated expression of uPAR in HMEC-1, an immortalized human dermal microvascular endothelial cell line (Kimberly et al., 2005).

GJA1 coding for the gap junction protein alpha 1 and found to be upregulated upon transient HOXA3 expression showed 46% correlation (correlation value: 0.464) with HOXA3 concerning the expression in response to the overexpression experiments.

Correlation found between HOXA3 and SMAD3 in terms of expression upon transient candidate gene expression accounted for 45% (correlation value: 0.453). The SMAD3 gene encodes a protein that belongs to the R-Smads or receptor regulated Smads. TGF- β signaling leads to activation of the SMAD3 protein by phosphorylation followed by heterodimerization with the SMAD4 protein. These heterodimers translocate to the nucleus where they regulate target gene transcription (Heldin, Miyazono and Dijke, 1997).

Correlation accounting for 42% was found between HOXA3 and CASP3 (correlation value: 0.429) in terms of expression in response to the overexpression experiments. CASP3 coding for an effector caspase was already shown to result in downregulated expression of HOXA3 upon transient expression of the CASP3 gene.

Genes found to show correlation of 40% with HOXA3 concerning their expression upon overexpression of the candidate genes were EPHA4 (correlation value: 0.406), PRSS23 (correlation value: 0.404) and IL-8 (correlation value: 0.396).

EPHA encoding the EPHA4 receptor, a member of the Eph family of receptor tyrosine kinases was already found to be upregulated upon transient HOXA3 expression.

PRSS23, also known as protease serine 23 encodes a serine protease that has been found to act as critical ovarian protease in vertebrates (Miyakoshi et al., 2006).

IL-8 coding for the chemokine interleukin 8 was also found to be upregulated as a result of transient HOXA3 expression.

Table 5. List of genes found to show highest correlation with HOXA3 concerning their expression as a result of transient candidate gene expression.

Position	Gene symbol	Correlation value	Position	Gene symbol	Correlation value
1	HOXA3	1.000	5	CASP3	0.429
2	SERPINE1	0.468	6	EPHA4	0.406
3	GJA1	0.464	7	PRSS23	0.404
4	SMAD3	0.453	8	IL-8	0.396

The respective genes are listed according to their correlation value, starting with the highest degree of correlation.

Figure 10. Single gene profile of correlation built for HOXA3. Values close to +1 indicated high correlation in expression whereas values close to 0 indicated poor correlation. Values found for correlation between HOXA3 and the other candidate genes in terms of expression in response to the overexpression experiments were smaller than 0.5.

5.4 HOXA3 in a gene network relevant to diabetic microangiopathy

In the course of the project aiming at identification of a gene network relevant to diabetic microangiopathy, a total of 37 candidate genes including HOXA3 were cloned into the expression vector pIRES2-EGFP and transiently expressed in iHUVESs prior to RNA-isolation from successfully transfected cells, reverse transcription and quantitative real time PCR of cDNA samples. Determination of the fold change was executed to analyze the effects of transient expression of a certain gene on the expression of the candidate gene set as it was shown in global and single gene profiles of both, expression and correlation without revealing direct or indirect regulatory interactions. In order to build a gene network represented by the adjacency matrix A , it was necessary to identify all the direct functional links between the candidate genes according to the formula:

$$A = \ln (D+I)$$

On the basis of regulatory interactions found between transiently expressed candidate genes (see appendix), it was possible to create a network comprising 37 genes (Figure 11), which was assumed to be of relevance to diabetic microangiopathy. This network demonstrated the most significant functional links between genes that might play a critical role in the occurrence of diabetic microvascular complications. The relative position of each gene within this network was determined according to the number of functional links between the respective gene and other genes. Functional links found between genes constituting the network represented activating or inhibitory effects. In addition, significant effects of the respective genes on their own expression were also demonstrated in this gene network relevant to diabetic microangiopathy. In order to be incorporated into the gene network, interactions between the candidate genes had to be greater than a certain threshold in terms of strength.

Table 6 describes the strength of direct functional links of HOXA3 to all the other candidate genes that were transiently expressed in the course of the project. The genes CFL1 and CASP3 were identified to be significantly involved in regulatory interactions with HOXA3. CFL1 encoding the protein cofilin1 was found to have an upregulating effect on the expression of HOXA3, whereas CASP3 coding for an effector caspase was described to have a downregulating effect on HOXA3 expression. Furthermore, a notable activating effect of HOXA3 on its own expression was demonstrated. Further significant

interactions of HOXA3 with candidate genes transiently expressed were not identified. Therefore, HOXA3 was found to take a peripheral position in the gene network, where its functional links to CFL1 and CASP3 as well as the activating effect on its own expression were demonstrated.

Table 6. Summary of direct interactions found between HOXA3 and all the other transiently expressed candidate genes.

from	to	strenght of interaction	effect	from	to	strenght of interaction	effect
CFL1	HOXA3	3.861057	upregulation	HOXA3	FZD4	0.239946	no effect

Only the most significant functional links of HOXA3 to other genes were incorporated into the gene network composed of 37 genes. Positive values greater than a certain threshold of 1.334 were considered to indicate activating effects whereas negative values smaller than a threshold of -1.130 were thought to reflect inhibitory effects.

Figure 11. HOXA3 in a gene network of possible relevance for diabetic microangiopathy. HOXA3 takes a peripheral position in the gene network since there is a smaller number of significant functional links between HOXA3 and the other genes involved. In this network, HOXA3 expression is demonstrated to be activated by CFL1 and inhibited by CASP3. Furthermore, an activating effect of HOXA3 on its own expression is demonstrated. In this illustration of the gene network, arrows indicate the direction of regulatory action. Upregulating effects are illustrated by continuous lines between interacting genes, Downregulating effects are indicated by discontinuous lines between interacting genes.

5.5 Western blot analysis and immunofluorescence staining of HOXA3

As mentioned above HOXA3 was found to be functionally linked to the genes CFL1 and CASP3 in a network that comprises 37 genes and is assumed to be of relevance to diabetic microangiopathy. Furthermore, a significant positive effect of HOXA3 on its own expression was identified. In order to verify these findings, Western blot analysis and immunofluorescence staining of HOXA3 protein were carried out comparing iHUECs transiently expressing HOXA3, CFL1 and CASP3, respectively, to untransfected cells.

5.5.1 Western blot analysis of HOXA3 protein

Western blot analysis of HOXA3 protein was done using cell lysates of untransfected and transfected iHUECs, where transfected cells were transiently expressing HOXA3 or CFL1 or CASP3. When compared to untransfected iHUECs elevated expression of HOXA3 protein was detected upon transient expression of HOXA3 and CFL1 (Figure 12). A downregulating effect of CASP3 on HOXA3 expression as it was demonstrated in the gene network was not confirmed since overexpression of CASP3 was not found to result in decreased levels of HOXA3 protein.

Figure 12. Western blot analysis of HOXA3 expression in transfected and untransfected iHUECs. HOXA3 expression is shown as a result of transient expression of CFL1 (lane 1) CASP3 (lane 2) and HOXA3 (lane3). When compared to untransfected iHUECs (lane 4), HOXA3 expression was found to be upregulated upon transient expression of CFL1 and HOXA3. Note that overexpression of CASP3 did not result in downregulated expression of HOXA3.

5.5.2 Immunofluorescence staining of HOXA3 protein

Cells successfully transfected with expression vector pIRES2-EGFP carrying the respective gene of interest showed a green signal as a result of EGFP expression.

When compared to untransfected cells (Figure 4d) immunofluorescence staining of protein encoded by HOXA3 in iHUVESs transiently expressing CFL1 (Figures 4a-1, 4a-2) revealed increased concentrations of HOXA3 protein in the cytoplasm and in the nucleus confirming the upregulating effect of CFL1 on the expression of HOXA3 as it was demonstrated in the gene network relevant to diabetic microangiopathy.

Elevated levels of HOXA3 protein were also found in iHUVESs transiently expressing HOXA3 (Figures 4b-1, 4b-2). In these cells especially the nucleus showed high concentrations of HOXA3 protein.

In contrast to Western blot analysis, immunofluorescence staining of HOXA3 protein was found to demonstrate a downregulating effect of CASP3 on HOXA3. When compared to untransfected cells decreased levels of HOXA3 protein were found in the cytoplasm and in the nuclei of iHUVESs transiently expressing CASP3 (Figures 4c-1, 4c-2).

Figure 4. Immunofluorescence staining of HOXA3 protein.

The concentrations of HOXA3 protein in the cytoplasm and in the nuclei of iHUVCEs transiently expressing CFL1 (a-1, a-2) or HOXA3 (b-1, b-2) or CASP3 (c-1, c-2) were compared to the levels of HOXA3 protein in untransfected cells (d). On the left side single channel images of iHUVCEs in red show the cellular distribution of HOXA3 protein represented by the red signal. Images of the same cells on the right side additionally depict in green the result of EGFP expression, indicating successful transfection with expression vector pIRES2-EGFP carrying the respective gene of interest. Cells transiently expressing CFL1 were found to have elevated levels of HOXA3 protein in the cytoplasm and in the nucleus. Increased concentrations of HOXA3 protein were detected in the nuclei of iHUVCEs transiently expressing HOXA3. Decreased levels of HOXA3 protein were found in the cytoplasm and in the nuclei of cells overexpressing the CASP3 gene.

6 Discussion

The idea of creating a gene network for diabetic microangiopathy was to demonstrate the interactions of functional relevance between candidate genes assumed to control the occurrence and course of microvascular complications. We could build a network composed of 37 candidate genes that had previously been identified in an *ex vivo* screen for transcripts regulated in BECs of diabetic *versus* non-diabetic capillaries. The position of each gene was determined by the number of its functional links to other genes involved and thereby provided information about the possible role of a gene in microvascular complications. Genes taking a central position within the network were considered to be key players in the occurrence of diabetic microangiopathy since they had a higher number of functional links than genes occupying a peripheral position.

Initially, a total of 125 candidate genes hypothesized to control microvascular complications was identified by gene expression profiling comparing (i) blood vascular endothelial cells (BECs) derived from tissue samples of diabetic and non-diabetic patients and (ii) BECs cultured *in vitro* under diabetic conditions, as well as by (iii) literature search. However, the fact that our final gene network was built from only 37 of these 125 identified candidate genes gives rise to doubts concerning the biological relevance of the network. The major point of criticism is that some important gene regulatory interactions may remain obscured as a result of the small number of genes constituting the network. Thus, it is unlikely that the regulatory interactions identified between the 37 genes within our network suffice to understand the whole process of gene regulation contributing to diabetic microangiopathy. However, this gene network can be considered as an important step to reveal the secrets of gene regulatory interactions controlling the occurrence of microvascular complications.

One reason for restricting the final gene network to barely 30 % of all identified candidate genes was the time consuming biological methods to obtain the data required for gene network construction. Each of the candidate genes had to be cloned into the expression vector pIRES2-EGFP and be transiently expressed in iHUEVCs. Successfully transfected cells were sorted by flow cytometry which had to yield at least 300,000 enhanced green fluorescent protein (EGFP) -positive cells for subsequent RNA-isolation. Isolated RNA was reverse transcribed and the resulting cDNA-sample was subjected to quantitative real time PCR, which was expected to deliver data essential for the construction of our gene network. Sometimes technical difficulties were found to delay the progression of the project. For example, for some of the candidate genes several unsuccessful attempts of cloning had to be

overcome, which were the result of problems occurring during PCR amplification or failure in restriction enzyme digestion.

As already mentioned, the candidate genes were cloned into pIRES2-EGFP prior to transient transfection of iHUECs. The reason for choosing this expression vector was the highly efficient detection of successfully transfected cells by flow cytometric cell sorting. The characteristic of pIRES2-EGFP is the presence of an internal ribosomal entry site (IRES) located between the multiple cloning site and the coding region of the EGFP. The consequence of this construction is translation of the gene that is cloned into the multiple cloning site and the EGFP gene from a single bicistronic mRNA.

Although diabetic microangiopathy seems to be the consequence of altered gene expression over a long period of time, the short duration of downstream effects upon transient candidate gene expression was considered appropriate to study the role of the respective candidate genes in the microvascular complications. This decision was a consequence of the fact that stable transfections of iHUECs in order to analyze the long-term effects of permanent overexpression of the candidate genes on the gene expression patterns of endothelial cells would have meant unrealistically great expenditure of time.

Human umbilical vein endothelial cells (HUECs) immortalized with the human telomerase catalytic protein (hTERT) were used for our transfection experiments. These cells were shown to largely maintain their endothelial character and therefore making them appropriate for the studies of diabetic microangiopathy (Aurea Burchard, personal communication). Moreover, iHUECs could be transfected at a reasonably high efficiency of up to 75 % with pIRES2-EGFP; which was in contrast to much lower results when using microvascular BECs. Still, the origin of iHUECs from the umbilical vein that normally is not subjected to diabetic complications is a drawback worth to mention. However, in principal we tested gene interactions that should be found in any condition, if gene products were of appropriate relative levels, i.e. not necessarily diabetes-specific. Thus, the iHUECs seemed to be a good compromise between technical feasibility and biological representativity.

Quantitative real time PCR was the method of choice in order to detect changes in candidate gene transcription upon transient gene expression in iHUECs. An alternative approach for measurement of changes in expression levels could have been the use of DNA chips. However, the higher costs of DNA chips as well as the lower accuracy and lower sensitivity of hybridization were the reason for choosing quantitative real time PCR for analysis of candidate gene transcription in response to the overexpression experiments. Moreover, from

the bioinformatical point of view quantitative real time PCR was more favorable for gene network construction than DNA chips, since this approach was expected to deliver more bits of information per data point than DNA chips. Thus, fewer data points were required in case of using real time PCR to accomplish the same accuracy when working with DNA chips (D'haeseleer et al., 2000).

In this diploma thesis a peripheral position of the HOXA3 gene within our 37 genes comprising network is reported. According to the gene network HOXA3 expression was directly regulated by the genes CFL1 and CASP3. Furthermore, an activating effect of HOXA3 on its own expression was suggested. CFL1 encoding cofilin1 that is known to contribute to cytoskeletal dynamics in nonmuscle cells (Hotulainen et al., 2005) activated HOXA3 expression. On the other hand, CASP3 coding for caspase 3, an effector caspase mediating apoptosis of pancreatic β -cells (Liadis et al., 2005), seemed to have a downregulating effect on the expression of the HOXA3 gene. In order to verify these findings Western blot analysis and immunofluorescence staining of HOXA3 protein were carried out. Both approaches involved transient transfection of iHUVESs with pIRES2-EGFP carrying the coding sequence of the gene suggested to regulate the expression of HOXA3. The levels of HOXA3 protein detected in cells transiently expressing CFL1, CASP3 and HOXA3, respectively, were compared to endogenous HOXA3 expression in untransfected cells. Western blot analysis and immunofluorescence staining of HOXA3 protein were not carried out for iHUVESs transiently transfected with empty pIRES2-EGFP. However, an empty vector control would have been reasonable for two reasons: First, initial determination of the fold change in gene expression was executed by comparison of Ct values obtained from quantitative real time PCR to those of a calibrator sample which was derived from iHUVESs transfected with empty pIRES2-EGFP. Second, effects of plasmid backbone on gene expression cannot be excluded. However, according to the single gene profile of HOXA3, no significant differences to untransfected cells treated with RPMI medium containing L-glucose were found to occur in terms of HOXA3 expression. Therefore, we still feel to be able to interpret correctly the possible role of HOXA3 within the gene network.

Specifically, three different experiments were carried out:

First, not unexpected, transient HOXA3 expression was also found to result in elevated levels of HOXA3 protein. On the one hand these higher amounts of HOXA3 protein could be the result of the additional exogenous expression of HOXA3 without any effect on the expression of endogenous HOXA3. On the other hand an autoinductive effect of HOXA3 on its own

expression could be the reason for the elevated levels of HOXA3 protein in cells transiently expressing HOXA3.

Second, Western blot and immunofluorescence analyses revealed activated HOXA3 expression in iHUVESs transiently expressing CFL1 when compared to untransfected cells. Third, Western blot analysis and immunofluorescence staining of iHUVESs transiently expressing CASP3 delivered different results concerning the effect on HOXA3 expression. Western blot analysis of cells transiently expressing CASP3 revealed levels of HOXA3 protein equal to those in untransfected cells. This unexpected result may be explained by the fact that cells used in these confirmation experiments were not subjected to flow cytometric cell sorting after transfection and therefore it is likely that a great amount of these iHUVESs assumed to be successfully transfected did not contain the expression vector carrying the CASP3 gene. On contrary, microscopic inspection of cells transiently expressing the CASP3 gene after immunofluorescence staining of HOXA3 protein revealed downregulated HOXA3 expression, when compared to untransfected iHUVESs. This latter result seems more significant, since the green signal of the EGFP protein detected in analyzed iHUVESs allowed identification of cells that were successfully transfected with pIRES2-EGFP carrying CASP3 coding sequence and exclusion of negative ones.

Three trials of transient HOXA3 expression followed by RNA-isolation, reverse transcription and quantitative real time PCR were compared with respect to the effects on candidate gene expression. Cells transiently transfected in the first trial were contaminated with mycoplasmas, whereas iHUVESs used in the other two trials were free from contamination. Considerable differences in candidate gene expression between contaminated and non-contaminated cells were observed upon transient transfection with pIRES2-EGFP carrying HOXA3 coding sequence. Small variations concerning the effect on the candidate gene set were found even between the second and the third trial of transient HOXA3 expression. These findings demonstrated the sensitivity of a cell line in terms of gene expression. However, these small variations between the second and the third trial of HOXA3 overexpression were found in expression of those candidate genes that were only slightly affected by transient expression of HOXA3.

Besides of the three interactions of HOXA3 with other proteins within the gene network, analysis of the effects of transient expression of HOXA3 on the 125 candidate gene set delivered interesting results. HOXA3 overexpression was found to result in activated

expression of genes encoding proteins that act in adipocytes. Adipocytes are known to serve as energy reservoirs by storing free fatty acids. Furthermore, these cells have been found to be of broader importance for health. Studies have revealed that adipocytes release various proteins that are critical for the regulation of metabolism. For example, enlarged adipocytes of obese individuals promote insulin resistance by production of proinflammatory factors and increased recruitment of macrophages (Greenberg and Obin, 2006). The expression of the genes EBF, SORBS1 and RHOJ was notably upregulated as a result of transient HOXA3 expression. The Rho GTPase encoded by the RHOJ gene is known to play a critical role in early adipocyte differentiation (Nishizuka et al., 2003). The EBF gene encoding the early B-cell factor has been shown to be expressed during adipogenesis, the process by which adipocytes are formed from preadipocytes (Jimenez et al., 2007). Studies have revealed a critical role of the SORBS1 gene in the regulation of glucose uptake by participating in insulin signaling in adipocytes (Baumann et al., 2000). The finding that HOXA3 activates the expression of genes regulating adipogenesis or being involved in insulin signaling in adipocytes suggests an important role of HOXA3 in the regulation of these processes.

Furthermore, HOXA3 might be involved in reorganization of the actin cytoskeleton since transient expression of HOXA3 was found to result in activated expression of the genes RHOJ (Vignal et al., 2003) and EPHA4 (Henkemeyer et al., 2003) which are known to regulate actin dynamics.

Vice versa HOXA3 was also found to be positively regulated by genes acting in adipocytes and contributing to actin dynamics, respectively, indicating that HOXA3 seems to be embedded in the regulation of these processes. Within the candidate gene set HOXA3 expression was notably elevated upon overexpression of CFL1 and KLF6 respectively. As already mentioned, CFL1 encoding cofilin 1 plays an important role in the regulation of cytoskeletal dynamics in nonmuscle cells (Hotulainen et al., 2005). KLF6 coding for transcription factor Krüppel-like factor 6 has been found to inhibit the proto-oncogene Delta-like1 (DLK1) in preadipocytes and thereby promoting adipocyte differentiation (Dan Li et al., 2005).

Previous studies revealed an angiogenesis promoting activity of HOXA3 by induction of endothelial cell migration. Constitutive expression of HOXA3 was found to accelerate the healing process of diabetic wounds in mice (Kimberly et al., 2005). These findings are supported by the activating effect of transiently expressed CXCL12 on endogenous HOXA expression as it was found in this diploma thesis. CXCL12 encoding the chemokine that is also known as stromal cell-derived factor 1 has been shown to mediate recruitment and

migration of endothelial progenitor cells as well as endothelial cells in response to ischemic injuries and thereby promoting angiogenesis. The proangiogenic signaling pathway is induced by binding of the CXCL12 protein to the CXCR4-receptor (Askari et al., 2003; Deshane et al., 2007).

In this diploma thesis, functional links of HOXA3 to the genes CFL1 and CASP3 within a 37 gene comprising network created by interdisciplinary cooperation between physicists, physicians and biologists were suggested.

In addition, a potential role of HOXA3 in biological processes including adipocyte differentiation and insulin signaling in adipocytes as well as reorganization of the actin cytoskeleton was found. Beside its function in embryonic development HOXA3 was known to be involved in angiogenesis and wound repair so far. Therefore, the results presented in this diploma thesis might open new perspectives concerning the function of HOXA3 in diabetic microangiopathy that could be analyzed in further studies.

Interactions between transiently expressed candidate genes were ranked according to their strength, starting from the strongest value of interaction. Certain threshold values for both, activating and inhibitory effects were set in order to incorporate only the most significant interactions into the gene network relevant to diabetic microangiopathy. Positive values representing activating effects had to be greater than a certain threshold of 1.334 , whereas negative values indicating inhibitory effects had to be smaller than -1.130. Three interactions involving HOXA3 were found to be significant for the gene network of relevance for diabetic microangiopathy. These were the activating and the inhibitory effect of CFL1 and CASP3 respectively on HOXA3 as well as a positive effect of HOXA3 on its own expression.

Abbreviations

7-AAD	...7-amino-actinomycin D
80K-H	...80 kDa protein substrate for protein kinase C
ABL	...Abelson tyrosine kinase
ADF	...Actin depolymerising factor
AGE	...Advanced glycation end product
ATPase	...Adenosine triphosphatase
ATP6VOD1	...D1 subunit of the transmembrane VO domain of ATPase
BCR	...B cell receptor
BECs	...Blood vessel endothelial cells
BSA	...Bovine serum albumin
CASP3	...Caspase 3
cDNA	...Complementary deoxyribonucleic acid
CFL1	...Cofilin1
CMV	...Cytomegalovirus
C1s	...serine protease (subunit of the multimeric C1 protein complex)
Ct	...Cycle threshold
CXCL12	...Chemokine (C-X-C motif) ligand 12
CXCR4	...Chemokine (C-X-C motif) receptor 4
DAG	...Diacylglycerol
DAPI	...4'6-diamidino-2-phenylindole dihydrochloride
DKA	...Diabetic ketoacidosis
DMA	...Diabetic microangiopathy
DNA	...Deoxyribonucleic acid
dNTP	...Deoxynucleotide triphosphate
ddNTP	...Dideoxynucleotide triphosphate
EBF	...Early B-cell factor
ECL	...Enhanced chemiluminescence
ECM	...Extracellular matrix
ECMV	...Encephalomyocarditis virus
EGFP	...Enhanced green fluorescent protein
eNOS	...Endothelial nitric oxide synthase
EPHA4	...Ephrin type A receptor 4

ET-1	...Endothelin-1
FBXO	...F-box proteins
FBS	...Fetal bovine serum
FC	...Fold change
FZD4	...Frizzled homolog 4
GAD	...Glutamic acid decarboxylase
GAPDH	...Glyceraldehyde-3-phosphate dehydrogenase
GCA	...Grancalcin
GFAT	...Glutamine:fructose-6-phosphate amidotransferase
GDM	...Gestational diabetes mellitus
GJA1	...Gap junction protein alpha 1
GSH	...Reduced glutathione
HMEC-1	...Human microvascular endothelial cell line-1
HOX genes	...Homeobox genes
HOXA3	...Homeobox A3
HOXD3	...Homeobox D3
hTERT	...Human telomerase reverse transcriptase
ICAM1	...Intercellular adhesion molecule 1
iHUVES	...Immortalized human umbilical vein endothelial cells
IL-1	...Interleukin-1
IL-8	...Interleukin-8
IPTG	...Isopropyl-beta-D-thiogalactopyranoside
IRES	...Internal ribosomal entry site
IRES2	...Internal ribosomal entry site 2
ITGA1	...Integrin alpha 1
KLF6	...Krüppel-like factor 6
LacZ	...Beta galactosidase
LB	...Luria Broth
MHC class II	...Major histocompatibility complex class II
MMP-14	...Matrix metalloproteinase-14
mRNA	...Messenger ribonucleic acid
NADP ⁺ /NADPH	...Nicotinamide adenine dinucleotide phosphate
NARS	...Asparaginyl-tRNA synthetase
NF-κB	...Nuclear factor-kappa B

NOS3	...Nitric oxide synthase 3
OGT	...O-linked N-acetylglucosamine transferase
OptiMEM	...Optimized minimal essential medium
OST-48	...Oligosaccharyltransferase 48kD subunit
PAI-1	...Plasminogen activator inhibitor-1
PARK7	...Parkinson disease 7
PARP	...Poly (adenosine diphosphate-ribose) polymerase
PAX1	...Paired box gene 1
PBGD	...Porphobilinogen desaminase
PBS	...Phosphate buffered saline
PCR	...Polymerase chain reaction
PFA	...Para-formaldehyde
PHGDH	...3-phosphoglycerate dehydrogenase
PKC	...Protein kinase C
PLD	...Phospholipase D
PRSS23	...Protease serine 23
p21 ^{Ras}	...21 kDa protein encoded by the ras gene family
RAGE	...Receptor of advanced glycation end products
RHOJ	...Ras homolog gene family member J
RNA	...Ribonucleic acid
ROS	...Reactive oxygen species
RPIB1	...Ribose-5-phosphate isomerase 1
RPMI	...Roswell Park Memorial Institute (development of RPMI medium)
SDS	...Sequence detection software
SDS-PAGE	...Sodium dodecyl sulfate polyacrylamide gel electrophoresis
SERPINE1	...Serpin peptidase inhibitor, clade E, member 1
SMAD3	...Mothers against decapentaplegic homolog 3
SMAD4	...Mothers against decapentaplegic homolog 4
SORBS1	...Sorbin and SH3-domain-containing-1
TARDBP	...TAR DNA binding protein
TBS	...Tris-buffered saline
TBST	...Tris-buffered saline Tween
TCA	...Trichloroacetic acid
TCA-cycle	...Tricarboxylic acid cycle

TNF- α	...Tumor necrosis factor-alpha
TGF- β	...Transforming growth factor-beta
UDP	...Uridine diphosphate
UGDH	...Uridine diphosphate -glucose dehydrogenase
UDPGlcNAc	...Uridine diphosphate -N-acetylglucosamine
uPA	...Urokinase-type plasminogen activator
uPAR	...Urokinase-type plasminogen activator receptor
VCAM-1	...Vascular cell adhesion molecule-1
VEGF	...Vascular endothelial growth factor
X-gal	...5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside

Curriculum Vitae

Personal information

Name: Andreas Thader
Date of birth: December 11th, 1978
Place of birth: Vienna, Austria
Address: Peter-Jordanstrasse 81/8/5
A-1180 Vienna
E-mail: andi.thader@chello.at

Education

2006 – 2008	Diploma thesis at the Institute of Clinical Pathology, AKH, Vienna, supervised by Nikolaus Wick, MD
Since 1999	University of Vienna Study of Biology (Microbiology and Genetics)
1998 – 1999	Vienna University of Technology (TU Wien) Study of Technical Physics
1997	High school diploma (Matura)
1989 – 1997	High school (Gymnasium und Realgymnasium) GWIKU Haizingergasse A-1180 Vienna
1985 – 1989	Elementary school (Volksschule) Bischof Faberplatz 1 A-1180 Vienna

Additional activities

1999 – 2006	Marginal employment (Billa supermarket)
1997 – 1998	Military Service for 8 months, Vienna
